we would put our Scarlet Runners in our herbaceous borders—but then we are not North American Indians. Once upon a time history tells us that the bulbs of *Camassia esculenta* were one of their principal articles of food. When, however, *Camassias* came to the Old World they were associated altogether with the flower garden. I cannot find that any attempt has been made to test the taste of these ancient plants. There is not a word about the Quamash in Robinson's translation of Vilmorin's book about vegetables, and we look for it in vain in Beckett's "Vegetables for Home and Exhibition"! I wonder if they have ever been served up at a British dinner-table! Quamash was the Indian word for the plant, and it would appear that the genus was originally called Quamashia ("Les Plantes Bulbeuses," by M. Bossin), to be in time changed by Lindley in 1837 into *Camassia*; and

"In spite of all temptations
To belong to other nations"

it seems finally to have adopted this as its family name. Thank you, Mr. Ker(Gawl), we are not Scillas. Thank you, Mr. Pursch, Phalangium is not in the same boat as *Camassia*. We are a bit proud of our family tree. Let us be thankful, then, that this is settled, and let us hope that it be like the laws of the Medes and Persians which alter not. It is very different when we come to species and varieties. It's just awful. Which is which, and which isn't t'other? must be left to the botanically inclined. The man in the garden can see a great divergence in the ways of the dying and defunct perianths. He sees some wrapping their segments carefully round the young seed vessels as if it were a pennyworth of precious lollypops in a paper bag and at the same time exuding some aqueous substance as if for further protection or future nourishment. He can see that certain plants have wider leaves than others and that some are taller and stouter-looking, whereas others are smaller and more slender. He notes differences in the colour of the leaves and flowers and, when planting, in the size of the bulbs. It is, of course, the various combinations of these factors that determine the various species and varieties, so it is easy to see that the possibilities of divergence are many. The prevailing colour of the family is some shade of mauve or purple, which in some cases gets very near a real blue. They flower at the same time as the later May-flowering Tulips and continue in bloom for a considerable period. Their spikes of flowers remind one of giant *Asphodels* or *Eremuri* in their general effect. They seem to be especially cut out for forming clumps in beds or borders amid other plants because of their contrast to the more usual occupants. They are ideal for what is called the semi-wild garden because they are very hardy, not at all particular about soil or position, content to remain where they are for a long time without deterioration and free seeders, thereby ensuring a numerous progeny with flowers delightfully varied in colour. All the different varieties should be planted in autumn and left undisturbed for three or four years. Although their stems are strong, they should not be put in very windy positions; but if they are, early staking must be attended to. *Camassias* seem to enjoy a slight amount of shade, but it is no necessity as certain books lead one to suppose. Now about what to buy! Few English catalogues provide much choice in the "fare" they offer. Even Suttons have only two, viz., *esculenta* with "bright mauve starry" flowers and *Cusickii* with "pretty pale lavender" flowers. If my names are correct, the colour of the flowers of the last named can hardly be called "pretty," certainly

not if they are compared with those of *Leichtlinii* Violet Queen or of *Leichtlinii* lilacea, which are bright and pretty, although just as pale. Messrs. Barr and Sons of King Street, Covent Garden, gave us a choice of six in their 1922 list. *Cusickii*, four *esculentas* and two *Leichtlinii*s.

Esculenta varieties may be known by the spread-eagling of their withering perianth segments—Bayley in his American Cyclopaedia of Horticulture says it is an undoubted and unerring "mark of the beast"—and by their lesser height compared with *Cusickii* and *Leichtlinii* varieties. They are very effective, more particularly those of a deep blue shade. *Esculenta atro-cerulea* and *Esculenta Blue Queen* are my favourites. As I have them named, both *Cusickii* and *Fraseri*

play second fiddle to the pale *Leichtlinii*s which I have already mentioned, *lilacea* and *Violet Queen*. But from some self-sown seedlings I know they are not the limit of this section's capacities. Two or three of my own are a fairly deep blue and look "champion" when their spikes are at their best. A curious feature about them is that their flowers appear to open by fits and starts, generally, if not always, beginning to expand in the early afternoon. I think this is characteristic of all the species except *esculenta* and its numerous varieties. *Camassias* seed freely and, as there is considerable variation among the seedlings, it is interesting to raise a few for ourselves. Seed may be sown either in the open air in early spring or in pans under glass in February. J. J.

THE CULTURE OF MUSCATS

AFTER some thirty years' experience in the growing of Muscats the writer is of the opinion that the only really satisfactory way to grow these Grapes is to raise them from "eyes" and follow throughout with pot culture. It a sequence of plants is arranged by striking a number of "eyes" each year or raising twice the number actually required, a constant annual supply of these delicious berries can be secured without extra labour or undue attention. Moreover, the troubles which are associated with the culture of Muscats with an outside Vine border are completely eliminated. That is to say, a sickly, unhealthy and premature yellowing of the foliage

vigorous they are less susceptible to the attacks of diseases and pests, with the result that the fruit matured is firm, well filled and luscious, and of good size, flavour and colour, and can be classed unhesitatingly as exhibition fruit. It is thought that some account of the cultural methods adopted might be useful to any growers who have not as yet tried the pot culture method for Muscats, therefore the following details are given.

PROPAGATION AND TREATMENT DURING FIRST YEAR.

A most successful method of propagation is by means of "eyes." These should be taken in January from well ripened wood. The buds should be cut out with about half an inch of woody tissue on either side of them, and should be inserted into soil in small thumb pots and plunged into a hot-bed in a forcing house with a temperature of about 75° (max.). The pots should then be covered with small hand-lights or bell-jars for a week or ten days. By this time growth will have commenced and a little air, enough to guard against a too rapid growth, should be admitted. It is important to keep the young plants growing steadily; too wide a range of temperature is often a cause of failure to establish them.

A POT OF MUSCATS IN ITS THIRD YEAR.

does not occur, neither are the rods so shy of bearing nor the bunches of fruit so liable to "tail off" or develop disproportionate "waists" as is the case where rods are kept indoors in one temperature and the roots outside in another. The writer is convinced that half the troubles attendant on the latter method of culture is due to this want of uniformity in the temperatures. Of course, where Muscats can be grown with their roots in an indoor culture-bed, the difficulty of temperature is overcome, but in small houses where space is wanted for other plants it is often impossible to spare space for such a bed.

At Lydney Park Muscats have been most successfully raised in large pots and fruited in their third year, when the number of bunches of fruit they are allowed to carry varies from four to six, representing a weight of 6lb. to 8lb. It is found that since the plants are young and

As growth proceeds, gradually raise the bell-glass or lights and, finally, remove them altogether. Next, gently raise the pots in the hot-bed until they can be stood on the surface. About March transfer the young plants to gin. pots and tie the young Vines to a cane. It is important that they should be potted up to exactly the same soil level as in the previous pots. The plants can now be allowed to grow ahead for about six weeks, during which time the pots should still be standing on the hot-bed and the temperature be maintained at about 60°. After this time repot into gin. pots and allow the access of plenty of light and air to the plants. Rapid growth will now take place, and when the young rods are about 6ft. high pinch out the leader. The plants will break behind this, and can grow unchecked for the rest of the season.

In early August transfer to 12in. pots, and to each pot apply ½lb. of half-inch bones, about ½lb. at the bottom of the pot to act as small crocks, and the other ½lb. distributed throughout

the remainder of the pot. This will ensure thorough aeration of the soil and promote drainage; moreover, the gradual disintegration of the softer portions of bone will liberate phosphates, which are valuable as plant food. The young Vines can now be stood in a light, airy house for about a month to ripen off the rods. After this period has elapsed stand the pots outside against a warm south wall, tying the rods up and plunging the pots into soil or ashes. They can be left thus for six weeks or so, when they should be heavily mulched with stable manure. This would be about mid-October, and the plants can be left outside until the end of December.

SOIL FOR VINES.

Undoubtedly the best soil for Vines is a stiff loam containing abundance of organic matter in the form of decaying root fibres. The soil in which Melons have been cultivated is excellent. This type of soil should be used throughout for the culture of Vines. When the plants exhibit signs of vigorous root activity it is often advisable to place semi-decayed turves on the top of the soil in the pots and on slates on which the pots stand, pressing them well up to the sides of the pots. The Vines root out very readily into this fibrous soil and make very strong, vigorous growth.

SECOND YEAR TREATMENT.

Some growers crop their Vines during the second year of growth, while others cut back and fruit them during their third year. The writer finds it most satisfactory to raise about a dozen rods and arrange them in the vinery, cutting back alternate ones to come into bearing in their third year and fruiting the remainder during their second year. These latter are staked and, as shewn in the illustration, trained to the roof, where about 3ft. of bearing surface is allowed to remain; this bears fruit in March. Each Vine carries three good bunches of fruit, and is cut back nearly to the ground in November.

Plants which are cut back at the beginning of the second year send out a vigorous young rod which, as in the case of the first year, is stopped at about 6ft. and then allowed to grow unchecked. Treat these Vines as during the first year with regard to hardening off, and when fruiting them during the third year allow them to carry four or five bunches of fruit. If more are allowed to remain the berries are not so fine or so well filled and the bunches are not so nicely shaped. The accompanying illustration shews five bunches of Grapes being borne during the third year by one Vine. After bearing, the Vines could be transferred to 15in. pots for further culture and treated as permanent Vines.

MANURING.

The best manures to apply to Vines are Peruvian guano and superphosphate. A little of the former should be given about every fortnight during the fruiting period and a light application of the latter at the commencement of the growing season. In order to avoid any tendency to souring of the soil, a little powdered lime may be occasionally applied and the surface of the soil lightly disturbed.

WILLIAM H. MILES.

CORRESPONDENCE

A GLORIOUS ROSE.

IN spite of the exceptionally late season, the new Hybrid Tea, Princess Victoria, has already started to bloom here, and the promise this Rose shewed last year is fully confirmed. The growth is splendid, not too erect, nor yet horizontal, the shoots almost following a regular angle of 45°, thereby making a very even and compact plant. The scarlet crimson blooms all seem to come of perfect shape and good enough for any exhibition box. The blooms also tone so well with the dark foliage and purple stems, in fact, the combination of bloom, foliage and growth is perfect. Had we but a Rose Test Garden there is little doubt that

Whitebeams are one of the most difficult groups of European plants to name, for the foliage varies so much in the same species and even on the same tree. Several kinds of great rarity grow on the limestone of the Wye Valley, about Bristol and near Cheddar. The genus *Sorbus* has been monographed by Professor Hedlund, and the best name for the common Whitebeam is *Sorbus Aria*, Crantz.—H. S. THOMPSON.

A REFINED AND BEAUTIFUL ANNUAL.

THAT charming Portuguese annual, *Cynoglossum linifolium*, has been the subject of much admiration of late among visitors to the

THE WHITE-FLOWERED CYNOGLOSSUM LINIFOLIUM.

this production of Messrs. McGredy would secure the highest award, and, in my opinion, as a good all-round Rose nothing better has been put on the market for many years.—HERBERT L. WETTERN, Oxford.

WHITEBEAM.

THE photograph of this handsome tree, on page 310, shews remarkably fine gradations of light and shade, often difficult to get in plant photography. In Surrey G. J. refers to the "strikingly conspicuous" corymbs of cream-white blossom; but about Bristol this year the blossom has been conspicuous by its absence, as has been more or less the case with many flowering trees and shrubs. In numerous cases both blossom and foliage were partially withered or destroyed by the cold winds and frosts of May, and in one district, resplendent last year with the blossom of Whitebeam in great variety, a week ago I actually saw no sign of flower or fruit.

As mentioned by me in a letter to the *Manchester Guardian* (May 12, 1923), *Sorbus* is a better generic name than *Pyrus* for the Whitebeams, Mountain Ash and Service Tree. English botanists have been slow in comparison with their Continental colleagues, who long since adopted *Sorbus* for these plants, and kept *Pyrus* more correctly for the Pear and Apple group; for there is a marked difference in the flowers, fruit and foliage. The

gardens at Gravetye. It is a graceful, effective and easily grown plant, however, sending up slender, wiry branching sprays of pure white flowers to a height of 18ins. Leaves and stems and even the bracts which persist at the base of the ripening burrs are of a delightful grey blue colour, rendering this graceful Hound's-tongue as distinct as charming during its period of bloom. The illustration shews a group of self-sown plants which survived the winter and are growing in poor, stony soil on a border raised above the ground level and in line with the eye. It is perfectly hardy and to have it at its best should be sown in September on the spot where it is intended to bloom, although it is certainly very pretty if scattered broadcast in spring, but in this case does not grow so high. Like the beautiful Chinese *C. amabile* it ripens seed abundantly every year and will renew itself on the spot if the soil is left undisturbed.—E. MARKHAM.

LATE-FLOWERING SAXIFRAGES FOR THE ALPINE HOUSE.

WHEN speaking or writing of late-flowering Saxifrages, one thinks mostly of the Encrusted varieties, which are second favourites to the Kabschia or Cushion section—perhaps in some people's estimation they rank first. They are certainly very useful for foliage as well as

floral decoration. Their silvery rosettes of leaves tend to relieve the monotony when there are no flowers in the early winter months and, in any case, they have an individuality which is interesting at all times. The Aizoon types, so far as my experience goes, are not for the alpine house; they seem to be more at home on the rockery. *Saxifraga Aizoon crustata*, however, makes a pretty foliage plant with its neat silvery rosettes. *S. cochlearis* flowers very well indoors. The white flowers are borne on erect stems, so that the plant has a stiff appearance, but if *Cotyledon simplicifolia* is arranged with it, the latter having drooping umbels of rich yellow flowers, it gives a very pleasing effect.

SS. lingulata and *lingulata lantoscana* ought to be in every alpine house. They make such a bold show with their arching sprays of white flowers and large rosettes of leaves. *S. catalanica* must not be forgotten. It flowers exceedingly freely in pyramids of fairly large white red-stemmed blossoms. As all the late-flowering Saxifrages are blessed with white flowers, it is really a good thing that there are other plants of different colouring that flower with them; such as *Campanula Steveni*,

I should think it would be hardy in the milder districts and on light, well drained soils.—*CALEDONIA.*

I HAVE been very much interested in the articles on "Fragrant Foliage," having for the last two years tried to collect as many kinds as possible in a tiny enclosed garden. I have Lavender, Rosemary, Balm (common and variegated), Bergamot, *Artemisia tridentata* and *A. arborea*, *Origanum hybridum* (apparently scentless), *Santolina*, Thyme, *Mentha Reiqueni*, *Phlomis*, *Salvia*, *Leimon Verbena*, *Perovskia atriplicifolia*, *Elsholtzia Stauntonii* (a charming little shrub), and an extremely unpleasant smelling *Laurus* called, I believe, *regalis*. The one thing I long for and cannot obtain is Balm of Gilead. Can any of your readers tell me where to find it?—*E. H.*

THE FLOWERING OF SAXIFRAGES.

I HAVE never in my long experience of growing my favourite Saxifrages, had such a mass of flower spikes as this season; this photograph of the upper part of a miniature "cliff," is almost entirely of a robust variety of *S. lantoscana*, with

A WONDERFUL SHOW OF ENCRUSTED SAXIFRAGE BLOSSOM.

with its large, well expanded blue flowers; *C. Raddeana*, with rich blue flowers on slender stems nearly a foot high; and *Onosma tauricum*, a charming alpine, admired by all who see it, not only for the delicious honey scent of the flowers, but also for their peculiar tubular shape—are particularly suitable. There are of course many others, such as *Gypsophila cerastoides*, *Lithospermum intermedium* and, in the shadier parts of the house, *Primula Bulleyana* and the graceful *P. sikkimensis*, which is still making a glorious display.—*R. C. JOLLEFF, Oxford.*

FRAGRANT FOLIAGE.

I HAVE been reading with interest and pleasure "Somers's" third contribution on the above fascinating subject. "Somers" says he only knows two of the Marjorams, viz., *Origanum vulgare* and its golden form. Might I be allowed to supplement these by indicating other two species which I have grown. The first is *O. Onites* (Pot Marjoram), too well known to require description; the other is *O. Dictamnus* (Dittany of Crete), a sweet-scented plant of procumbent habit with pinkish flowers. As I grew it in the conservatory both as a hanging plant and for draping, I cannot speak as to its hardiness, but

some sturdy spikes of the rare *S. catalanica* (true) in the lower part to left. In the winter the silvery rosettes on this little cliff give constant delight to the eye of the Saxifrage lover.—*KENNETH ROGERS.*

IS GLADIOLUS BRENCHEYENSIS HARDY?

AN enquiry recently appeared in this column as to garden experience of the hardiness of *Gladiolus brencleyensis*. I know of a fine group of this plant which has stood in the open out of doors for twenty years. A bulb was accidentally introduced into an Asparagus bed and was allowed to remain and flower year after year. Two years ago, when the bulbs had become a congested mass and some were visible on the surface of the bed, a hundred good bulbs were removed to a flower border, where they have since continued to thrive without protection. Some "spawn" or small bulbs must have remained in the Asparagus bed, for there is now a thicket of young plants coming up in the old place. The bed has, of course generally received a mulch in winter, but for some years it did not receive even this amount of protection. The garden I speak of is on cold, chalky soil in Wiltshire, high up near the edge of the downs, and hangs towards the north, so it is by

no means a specially favoured spot. Does not this suggest that *Gladiolus brencleyensis*, if given some protection until thoroughly established, might be more commonly treated as a hardy plant and left in the ground year after year. I should add that the bulbs thus treated flower magnificently and rather earlier than replanted bulbs.—*W. ARNOLD-FORSTER*

GREEN GOOSEBERRY JAM.

I THINK, perhaps, the following recipe for green gooseberry jam may be of interest: Trim and wash 3½ lb. of green (unripe) Gooseberries. Place in preserving pan with five breakfastcupfuls of water. Boil water and fruit one hour. Add sugar and again bring to boiling point, then boil for one minute only. If boiled over the minute the preserve will turn pink and its charm will be gone.—*C. C.*

PELARGONIUMS WITH BEAUTIFUL FOLIAGE.

"WHERE are the friends of my youth?" was Dean Hole's opening line in an article of his on "Old-time Roses," and the same thought was in my mind on reading the interesting note by Mr. W. Linders Lea on page 251. I well remember Tricolor "Geraniums" of fifty years ago. As a young chap they were my hobby, and I had a good collection of the best sorts. Mrs. Pollock was the first to be sent out, followed by *Sophia Dumasque* (one of the best), *Lady Cullum* and many others of which I cannot remember the names. Mrs. Pollock was a seedling raised by Mr. Grieve. Probably the best of the silvers was *Italia Unita*. Tricolors used to be well shewn by the late Mr. Charles Turner of Slough. At the Reading Show in the old Abbey ruins he once staged some fine specimens, trained flat like a cart-wheel, as Pelargoniums used to be shewn in those days, and fully 2 ft. across, brilliantly coloured. The plant of *Lady Cullum* was particularly rich in its scarlet, black, yellow and green colours. Many fine varieties originated at Reading, for the Curator of the Forbury Gardens, a Mr. Davis, was a very successful raiser of seedlings which found their way into the trade. About thirty years ago I saw at Heaths at Cheltenham a fine stock of these Pelargoniums, the principal variety being Mrs. Cox, and evidently from the large quantity grown there must have been a good demand; it seems strange they should now be little more than a memory. Possibly the turn of the wheel of fashion may again bring these beautiful plants into favour. All they require is the ordinary treatment of bedding Pelargoniums, to be grown close to the glass, with all the sun and air they can have to bring out the bright colouring of the foliage and, as Mr. Lea points out, a flower spoils them.—*J. P.*

A BEAUTIFUL ASTER.

I CONSIDER one of the most charming of the more recent introductions in Asters to be *A. Farreri*. This is an excellent plant for rock garden or margin or border and, while it is perfectly hardy, it appears to delight in any well drained, gritty loam with full exposure. The leaves are a rich green, somewhat long and narrow, pointed and hairy. In the later spring flower-stems rise to about 1 ft. in height with a pendent bud, which latter, as it assumes the perpendicular, expands into the large and handsome flower. The rays of this lovely blossom are long and narrow, of a rich violet-blue, and they are disposed in that touzled, informal kind of fringe which is often so much more attractive than that of the stiffer, more conventional form. The centre of the bloom is a full, warm orange surrounded with an "iris" of neutral tint.—*N. W.*

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Parsley.—A few lines of Parsley should be sown to furnish leaves during the winter months, and a position sheltered from the east is preferable, while the seed-bed ought to be so arranged that a cold frame can be put over the plants in winter if necessary.

Potatoes.—When the early crop is lifted sufficient tubers should be set apart for "seed" next season, and those about the size of a hen's egg are best. They should be placed in the store-room or shed, and need not be covered. In preparing the ground for other crops a levelling of the soil is all that is necessary.

Seakale.—If strong crowns are required for early forcing, the plants will now need every attention. The soil should be deeply hoed, and where there are a number of growths on each plant they should be reduced to one without further delay.

Vegetable Marrows.—During a spell of dry weather the plants will need a copious supply of water, and when the fruits are set a weekly application of liquid manure will be beneficial. To hasten the formation of fruits the growths may be pinched at the first leaf after the appearance of a female flower. Another batch of plants may be put out for succession.

Endive.—The main sowing of this salad should be made at this season, and a later one in July or August. It is most valuable during a severe winter when Lettuce is killed or rendered unfit for use until spring. The seed should be sown in drills six inches apart and the seedlings thinned to the same distance. A light rich soil is advised for Endive, but tolerably good results are obtained from most gardens. Endive should be carefully blanched before it is sent to the kitchen, and a good method is to tie up the plants loosely and then cover with an inverted flower-pot. At the same time place a piece of slate over the hole of the pot to exclude light. Only a few plants ought to be done at one time, because directly it is ready it must be used or the plants will decay.

The Flower Garden.

Viburnum Carlesii.—This is a delightful shrub which should find a home in every garden, but the object of this note is to draw attention to any suckers that may be forming at the base of the plant. As a rule it is grafted on the common Viburnum, and this stock is most troublesome in producing suckers. Lilacs and Rhododendrons which have been grafted are afflicted in the same way. All suckers should be removed or they will soon destroy the plant one wishes to grow.

Gladioli.—These should be staked and tied up before they are likely to be damaged by wind, for once they are bent over they rarely fully recover their symmetrical appearance. Heavy stakes are not needed.

Violets.—The moist conditions prevailing at the time of planting out gave the runners a good start, and now if the weather is dry a sharp look-out must be kept for red spider, which is the Violet's worst enemy. The plants may be syringed over each evening, more especially after a hot day, and given an occasional dusting of soot, when red spider will rarely appear. Keep the ground free from weeds and remove all runners as they appear, which will assist the plants in building up strong crowns. Where the soil is poor weak liquid manure will be beneficial.

Chrysanthemums.—The early-flowering varieties are well nigh indispensable to gardens, particularly where cut flowers are needed in the autumn, and every effort should be made to produce useful plants for this purpose. Early staking is essential, and after this date no further stopping is necessary. Give a thorough hoeing and then mulch the roots with decayed manure or leaf-mould, while water will be required if the roots become dry.

The Hardy Fruit Garden.

Gooseberries, etc.—Excellent fruit may be obtained from small fruits grown as cordons. They may be trained to wires or on a wall, while if some are placed on walls with a cool aspect the fruiting season is prolonged. This remark applies especially to Red and White Currants, and the former if protected from birds will keep in good condition till late in the autumn. During the next week or two these trees may be summer pruned, which consists of stopping the side growths

at the fourth leaf, but the leaders may be allowed to extend for a few more weeks. If insect pests are present, the trees should be cleansed thoroughly with a non-poisonous insecticide, afterwards giving them a good hard syringing with clear water. If the roots are approaching dryness, give them a soaking of water, hoe the soil, and then afford a mulching of decayed manure or any material that will conserve moisture. Bush trees of Gooseberries and Red and White Currants may also be pruned, but Black Currants should not be touched till the fruit is gathered.

Fruits Under Glass.

The Orchard House.—The centre of this house being used for pot trees, the time has arrived when some of them will be producing ripe fruit, and when this is gathered the trees ought to be transferred to their outside quarters. Plunge the pots and keep the roots moist, while during dry weather the foliage should be freely syringed. Freedom from red spider and other insects is essential.

Vegetables Under Glass.

Cucumbers. Where the plants are showing signs of exhaustion they should be rooted out, and after fresh soil has been provided, young plants be set in position to provide future crops. Cucumber plants are so easily raised from seeds at this season that any unproductive plants should be discarded at once. Those in full bearing may be assisted with some reliable fertiliser or weak liquid manure, while at all times the roots should be liberally supplied with moisture. Syringe the foliage with tepid water twice each day, and close the house between three and four o'clock. A thin shading is advised during very bright weather.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),

Castleford, Chesham, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Seakale.—Make sure that young plants have all been disbudded thoroughly. This means that the buds have been reduced to one and the strongest retained. Go over established plants that are to be blanching in the open and cut away any flowers that have developed on uncut crowns. A light dressing of salt in showery weather will be helpful to this plant.

Cauliflowers.—Where plants are showing any signs of being attacked by the maggot of the cabbage fly the following antidote will generally arrest the evil: Dissolve two heaped tablespoonfuls of Epsom salts in a little hot water and add this to a gallon of cold water. Pour alongside the stem of the suffering plant sufficient of the solution thoroughly to wet the affected part. The provoking thing is that in dull, cloudy weather the damage cannot be detected until a bright day comes round, when it is irreparable. Early planted stock will now be turning in for use, and if they develop more quickly than is desirable, break some leaves over the curd to preserve its whiteness till they can be used up.

Vegetable Marrows.—As the main shoots extend peg them down carefully to prevent them being blown about and damaged by high winds. Keep a sharp look-out for the appearance of female blossoms, which shew the embryo fruit at their base. Promptly after the opening of a female flower pick a male one (they are generally plentiful), tear away the corolla, and lightly touch the stigma of the female blossom with the pistil. Fructification will almost certainly result.

General Work.—The principal work for some time to come will be that of keeping crops clear of weeds by hand-weeding and hoeing, the latter operation serving the double purpose of keeping down weeds and aerating the soil. Certain crops, such as Onions, will be benefited by occasional applications of some weak stimulant, and if a spell of dry weather sets in watering should be resorted to.

The Flower Garden.

Autumn Crocuses.—There is such a wealth of variety of the common spring mongrel Crocuses that we are apt to overlook the merits of the scarcer distinct species, some of which flower in spring and some in autumn. Of the latter section *C. speciosus* is one of the best, its lilac flowers and rich golden anthers being very attractive. This species is also a splendid "doer," increasing rapidly in a suitable environment. *C. pulchellus* and *C. Tournetii* are also among the best. As the corms of these autumn species should be planted during July, those intending

purchasing should lose no time in securing their supplies. If it is intended to purchase any of the *Colchicums*, they should also be ordered now. *C. Bormulleri* and *C. speciosum* are two of the best.

Carnations. Seedlings in their earlier stages are very subject to attacks by the Carnation maggot. This pest commences its operations on the leaves and gradually bores its way into the stems. Its presence can be detected by whitish marks on the leaves, and when seen it should be squeezed with the thumbnail.

Roses will now be commencing to open their flowers, and as it is undesirable to interfere with the plants during the flowering period they should be looked over for pests and, if present, they should be promptly dealt with. Any Briar suckers should be removed immediately.

Hollyhocks are gross feeders, and are much benefited by occasional doses of weak liquid manure. Tying should also be attended to as the rapid growth proceeds, and previous recent tyings should be slightly readjusted or the shoots are apt to get deformed. Any leaves that are badly infested with the dreaded fungus should be removed.

Fruits Under Glass.

Figs. Trees which were started early and have had the advantage of a fairly brisk temperature should now be showing ripe fruit, so drier conditions both at the roots and in the atmosphere should be maintained until the crop is picked. If the work of disbudding has in any way been neglected, the pruning knife should be used to remove any surplus or badly placed young shoots. If the young shoots retained are pinched, it will encourage the production of fruits for the second crop and will facilitate the process of swelling them.

Melons.—Mid-season crops will now have set their fruits, and these should be supported by nets as soon as they have attained the size of pigeons' eggs. From now until the fruits are full size they will require liberal supplies of water at the root, with weekly applications of weak liquid manure. Shoop droppings are very suitable for this work. Guano water at the rate of two teaspoonfuls per gallon also gives good results. The house must be well charged with atmospheric moisture morning and afternoon to keep red spider at bay. Pinch out all young laterals and sub-laterals as they appear. Tie the shoots of second crop plants as they advance.

The Orchard House.—As the earlier trees ripen their fruits and are harvested the pots or tubs should be moved outside and the trees be vigorously syringed. Afterwards the trees should be stood in full sunshine on a layer of coal ashes, so that the wood may get thoroughly ripened. The vacancies thus caused in the house might be filled up with late Tomatoes which have been standing rather thickly elsewhere. Fire-heat may be entirely dispensed with now, when less atmospheric moisture will be required.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian.)

GREENHOUSE AND CONSERVATORY.

Salvias.—Several species are very useful for supplying flowers during the autumn and winter; especially in the country, where winter fogs are not troublesome. In the immediate neighbourhood of London their successful flowering is very uncertain, as one night's fog is sufficient to strip them of every flower and bud. *Salvia splendens* and its varieties are most popular. Where large specimens are required, the plants should now be got into their flowering pots, or they may be planted out in a piece of rich ground, lifting and potting them up towards the middle of September. The best ones for large specimens are *S. splendens* and its variety *pyramidalis*. It is also worth while to grow a few plants of *S. splendens violacea*, with its violet-purple flowers. Where small plants are required for the stages, preference should be given to one of the good dwarf varieties. *Glory of Zurich* is as good as any. This variety comes into flower very quickly, and if raised from cuttings at this season will make good, useful plants for late autumn. Other useful *Salvias* for flowering during the winter are *S. azurea* variety *grandiflora*, *S. involuta* variety *Bethelli*, *S. rutilans*, *S. leucantha*, *S. Greggii* for autumn flowering, and *S. Heeri*, which flowers early in the New Year. They all succeed under the same treatment and if grown in pots should be stood out on a bed of ashes, partly plunging the pots to prevent them blowing over.

Sparmannia africana, which is so useful for flowering in winter, should now be stood outdoors in a sunny position to enable the wood to become thoroughly ripened, as this is the only way to ensure its flowering freely. Plants rooted early this year should now be established in their flowering pots, which should be 6 in. or 7 in. in size. Such plants in their first year are very useful for furnishing the stage.

Coleonema album.—This South African plant is very useful either as a small plant or as a large specimen for furnishing the conservatory. It makes a neat, compact plant with slender heath-like shoots, and produces its small, white flowers very freely. Unlike many hard wooded plants its successful cultivation presents few difficulties. It soon makes a large specimen if planted out in a bed in the conservatory. It may be easily propagated at this time by means of half-ripened twiggy shoots, inserted in pots containing sandy peat which should be stood under a bell glass in a cool house.

Coronilla glauca and its variegated form are very useful for greenhouse decoration; *C. valentina* is also suitable for the same purpose. They are both hardy against a wall in the west, but in colder parts of the country they require the shelter of a cool greenhouse. They are easily propagated by means of half-ripened twiggy shoots, inserted in pots containing sandy soil and stood under a bell glass in a cool house. The young plants should be pinched several times to lay a good foundation for the future.

Cosmos bipinnatus.—Although generally grown outdoors in beds or borders, this plant is well worth growing in pots for furnishing the conservatory during the autumn months. For this purpose the required number of plants should now be put into 10 in. or 12 in. pots. During the summer months they should be plunged out in an open position and given the same treatment as *Chrysanthemums*. The plants should be well staked and kept regularly tied, as the side shoots are apt to break off at the main stem. These plants are very useful for giving a supply of cut flowers. The early-flowering forms are best for outdoor cultivation; the ordinary and later-flowering type may, with advantage, be used for indoor work.

Lavatera thuringiaca is the species that is generally grown and shewn as *L. Olbia*. Although more or less hardy in the South, it usually gets cut to the ground during the winter. Grown in pots, it is now in flower, and its soft pink blossoms are freely produced. After flowering, the shoots should be partly shortened back, and when the lateral shoots are some 3 ins. in length they should be secured as cuttings. These root readily in a close case in a cool house. The young plants grown on make useful specimens for the following year. If large specimens are desired, the old plants should be grown on; they only require the shelter of a cold frame or cool house.

Royal Botanic Gardens, Kew. J. COURTS.

DWARF FRENCH BEANS

Late sowings of these Beans yield crops that are much appreciated.

EARLY sowings are general and very often failure follows, so that the most satisfactory results are obtained when the young plants can be grown without any serious check. For many years I made a point of sowing seeds at the beginning of July and again at the end of that month. Of course, a sheltered position for the plants is essential. Rarely will the plants resultant from the early July sowing fail to yield a good crop, while those from the later sowing will also prove satisfactory if the months of September and October are favourable as regards normal weather conditions. In the northern counties it is not advisable to sow seeds after the first week in July.

Early varieties should be sown; I found *Ne Plus Ultra* and *Canadian Wonder* answer well, the latter for early date sowing and the former for the later sowing.

If the soil is really in a poor condition well rotted manure must be dug in; but soil of medium richness, or that previously manured for a quick-maturing crop, will do for our purpose without

further attention. Usually, old kitchen garden soil will do nicely for dwarf Beans.

A border facing south and with a wall or close fence on the north, is ideal for this late Bean crop. I favour sowing the seeds in single rows, 6 ins. from seed to seed and 20 ins. between the rows. If the soil is very dry pour water in the open drills, sow the seeds and cover with the dry soil, but do not water afterwards. Germination will be rapid, and the plants will grow sturdily and be self-supporting. Before they have a chance to suffer from lack of moisture apply a mulch of rotted manure 2 ins. or a little more in thickness. The pods are very tender and they will be exceptionally numerous on every plant treated in the manner described.

GEO. GARNER.

Sweet Rockets.—Though now seldom seen, the old double Sweet Rockets (*Hesperis matronalis*) are among the very choicest of the border flowers of generations ago. The usual colours are white and purple, but there are, or were, two distinct forms of these in cultivation, the older and more precious one being dwarfier and stockier than the other. That this form in particular is now rare must be regarded with no little regret, for its compact heads of double flowers, like those of a Ten-Week Stock, were deliciously fragrant, and the plant was invested with that quiet charm which belongs to old-time flowers. As with many of the old double Wall-flowers, these Rockets appear to have lost vigour owing to long continued propagation by cuttings, but they also seem to resent and to dwindle under the enervating influence of our more southerly districts, since what remains of their strongholds are still in the north. The single-flowered, typical plant, on the other hand, is still as robust as any weed, which it will soon become in most gardens. Albeit, this is a handsome and fragrant plant for naturalising in grass or rough places in company with *Valerian* (*Centranthus*), *Campanula macrantha* and *C. lactiflora*, *Willow Herb* and such like.

A Too Little-Known Greenhouse Climber.—It would almost appear, from the absence in many greenhouses to-day of those beautiful climbers, the *Chorizemas*, that they are either not known or that gardeners look upon them as needing more heat than they can afford. Probably the latter theory is the correct one, as the orthodox method of growing them, and the one which obtained exclusively forty years or more ago, was to house them in the humid, heated atmosphere of the stove. Readers are reminded that the same practice was followed with many other plants that to-day are grown with very satisfactory results in the greenhouse—*Hoyas*, *Gloxinias* and *Streptocarpuses* among the number. The *Chorizemas* are among the most charming of the Australian climbers, and are well served if planted in large pots or tubs in peat and loam and sand and allowed to clothe a pillar or ramble on the rafters of the house. The flowers (a delightful combination of red and yellow in *C. varium*) are freely borne once the plants are established, and the plants are worthy of inclusion in any greenhouse where the winter temperature does not fall far below 55°.

A Handsome Sedum.—There are few of the later-flowering and hardier Mexican *Sedums* which can compare with *S. compressum* in size and beauty of foliage and flower, and this is one which can stand our winters and inclement springs better than most of its class. *S. compressum* is an evergreen, perennial species with semi-prostrate stems which rise to some 6 ins. to 8 ins. in height. The leaves of the rosettes are about 3 in. wide, apiculate, slightly glaucous and fleshy and of a pale lettuce green, the older ones being flushed

with red and beaded at the margins. The flower-stems ascend to about 6 ins. above the rosettes in May (where the climate is a genial one), and these branch and produce copious heads of buds which open with the first warm days of the later spring into a dazzling array of rich orange yellow blossoms, each one of which is nearly half an inch across. *S. compressum* in full flower is a most striking and beautiful object, and there is little doubt but that this species would be more widely grown were its fine qualities and ease of culture more generally realised. A light, gritty soil and sunny situation are desirable.

Potentilla nitida.—This is one of the choicest of the great *Potentilla* family, but, being a high alpine, it is not among the easiest to grow in every garden. It will, however, generally prosper in a free, gritty soil containing plenty of old mortar and where there is free exposure. In any event it is a plant of such superlative charm that it merits infinite patience and care. In some gardens where *P. nitida* had been almost given up in despair it has flourished quite extraordinarily when planted in close contact with other plants of similar nature, which suggests that isolation on some arid rock-garden ledge is inimical to its welfare. *P. nitida* makes a close-set mat of silken, silvery trefoil leaves 1 in. or so in height, just clear of which the lovely flowers are borne in early June. In the best forms these are a clear rose pink, but there are others in a number of intermediate colours between that and the pink-eyed, pearly white kind often listed as *P. Clusiana*. The latter may, however, be distinguished from *P. nitida* by its leaves, which have five lobes instead of three.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

ANTIRRHINUMS ATTACKED (G. B. B.).—The *Antirrhinums* are attacked at the base by the disease caused by the fungus *Phytophthora cryptogea*. The best way to avoid this trouble is always to use fresh soil, give plenty of air and light and never overwater.

LILIAM CANDIDUM FAILING (H. D.).—The failure of *Lilium candidum* is probably due to the disease *Botrytis cinerea*. In the early stages of the disease the plants should be sprayed with liver of sulphur (Potassium sulphide), using 4 oz. to 1 gallon of water. Add also a little soft soap to the mixture. The plant sent for naming is a variety of *Verbascum Chaixii*.

GERANIUMS UNSATISFACTORY (G. P. and Sons).—The spots on the *Geranium* leaf sent appear to be abrasions due to thrips. None is present now, but if they recur fumigation if indoors, spraying with a nicotine wash if outdoors, is necessary.

ENGLISH IRISES (Folsted).—These *Irises* will thrive in partial shade, but do better in a more open quarter. In October they should be planted 3 ins. deep—the covering soil should not be deeper. They increase and may be left in a suitable soil for two or three years, then lifted, separated and replanted in another border or part of it.

PYRETHRUMS UNSATISFACTORY (B. R.).—*Pyrethrums* will succeed in any ordinary garden soil. In clayey loam the planting is best done towards the end of February. In our correspondent's case the plants should be put in late in the autumn or early in winter, taking care to do this work when the soil is fairly dry and not in frosty weather. The mat-like roots should be opened out and some fine soil worked in among them, making all soil firm. Pack old cinders and ashes round the crowns and a thin layer on them to prevent slugs eating the crowns and the new shoots in spring.

SWEET PEA FLOWER-BUDS DROPPING (H. I.).—Very frequently the first-formed flower-buds fall prematurely for the following reason: the growth of the plant being rapid at this stage overcomes the bud, the latter turns yellow and drops off. In the meantime many more buds are forming, and they to some extent arrest the growth of haulm; nourishment is more equally divided between the two and the flowers develop. Any check through coldness of soil or air coupled with too much moisture at the roots will cause bud-dropping.

ROSE GARDEN.

ROSE HUGH DICKSON UNSATISFACTORY (O. B.).—The foliage of the *Rose* sent appears to have been damaged by cold winds. The malformation of the flowers may arise from improper pruning or from permitting too great a number of flowers to remain on the bushes.

THE GREENHOUSE.

PLANTS FOR FLOWERING IN THE GREENHOUSE IN WINTER (F. W.).—Our correspondent may buy a few plants of *Chrysanthemums* now and grow them in the open air till October; also some Perpetual-flowering *Carnations*, placing them on a bed of ashes till August, repotting if necessary and transferring to the greenhouse during the last-named month. With regard to *Hydrangeas* and *Regal Pelargoniums*, young plants of the former should be bought and a few old ones of the latter to propagate from in the summer. The *Azaleas*, too, should be bought in the autumn to flower in due course, as cuttings of these would be useless. Several plants on each of the following would ensure a varied and bright display: *Cinerarias*, *Primulas*, *Cyclamens*, *Kalanchoe carnica*, *Genistas* and *Sparmannia africana*. The young plants of *Canterbury Bells* are best retained in pots throughout, repotting till the flowering size is reached.

TREES AND SHRUBS.

CLIPPING YEW HEDGES (L. H.). The ordinary clipping of Yew hedges with shears may be done at any time between May and August as often as required. When hard cutting back into the older wood is contemplated, this is best done in May when new growths are beginning to push.

PLANTING A YEW HEDGE (A. G. C.). Our correspondent's letter descriptive of the planting of the new Yew hedge suggests that the cause of failure may be one, or partly all three, of the following reasons: (1) Yew should be moved with good balls of soil attached to the roots. (2) Planting should be done in early September so that new roots are made before winter, but May is an even better month to plant Yew hedges. (3) The autumn of 1922 was damp and showery, but newly planted Yews would require a thorough watering several times at intervals of a week. The rain at that time was not sufficient to reach the roots. If there is still life in the plants much with a mixture of old decayed manure and leaf-mould; afterwards water freely.

WILD GARDEN.

NATURALISING THE PURPLE ORCHIS (S. H. A.).—The Purple Orchis (*O. mascula*) requires heavy loam in pasture land. The best time for transplanting is as soon as the foliage has turned brown and the new tubers are formed. Plant them in little groups, not singly. Flowering plants from seed take two or three years to develop. The flowering of *Orchis* species is very erratic. Some years very few are seen, while the next season they may be very plentiful. *O. mascula* may be obtained from Mr. G. Reuther, Fox Hill Nursery, Keston, Kent.

FRUIT GARDEN.

PLUM SUCKERS (Folsted).—The suckers from the old Plum plantation will probably be from the Mussel stock. In the winter they may be divided and replanted to form a wind-break. In this respect they would answer better than Danions, but for fruiting the latter should be planted.

FRUIT UNDER GLASS.

PEACH TREE UNSATISFACTORY (P. H. T., Goring).—Probably the tree is attacked by silver leaf; but, to make certain examine the wood some distance from the affected leaves. A brown stain indicates the presence of *Sterium purpureum* (silver-leaf fungus). Remove the branch behind the place where the brown stain is apparent and paint over the wound with tar or lead paint.

PEACHES AND NECTARINES UNSATISFACTORY (J. H.).—The flowers of the Peach and Nectarine appear to have been fertilised properly, but the embryos are now dying and so the fruits drop. Lack of water may be a cause or, possibly (but from their appearance we do not think it probable), insufficient lime.

MISCELLANEOUS.

SOIL TURNING GREEN ON SURFACE IN POTS (H. P., Hants).—It is the natural greenness of the soil that causes the surface to become green and slimy after it has been watered in the pots for a time. Coarse silver sand is better than builders' sand, especially as the soil is fibreless. Leaf-soil half decayed would be better than peat. In addition to the sand, use, in moderation, some old mortar rubble broken up rather finely.

NEW ZEALAND PLANTS (Mrs. W., Heston).—*Kowhai*, yellow (*Sophora tetraptera*) is a half-hardy deciduous tree, 6ft. to 12ft. high, with pinnate leaves and yellow flowers. Requires the shelter of a wall in the colder parts of this country. *Pohutukawa* (*Metrosideros tomentosa*) is a tree growing 30ft. to 40ft. high, with narrow, oblong leaves and rich crimson flowers in terminal, many-flowered, dense cymes. July. Greenhouse plant. *Scarlet Ti Tree* (*Cordyline indivisa* var. *atropurpurea*) has stems 6ft. or more high with heads of long strap-shaped leaves 2ft. to 4ft. long. Hardy in the south-west. *Eucalyptus leucocorydon* (Iron Bark, White Gum).—A medium-sized tree with lance-shaped leaves and yellow flowers. A greenhouse plant, only hardy in warmer parts. *Scarlet Flax* (*Phormium tenax* var. *atropurpureum*).—A tufted perennial with long iris-like leaves, 3ft. to 6ft. long, purple in colour, with a reddish tinge. Flowers red, on a tall panicle in August. Hardy in sheltered places. *Rock Lily* (*Arthropodium carthartum*).—A greenhouse perennial with tufts of spreading narrow leaves 1ft. long. Flowers white, in branching racemes, 3ft. high. All the above require greenhouse treatment in the colder parts of the country, but may be grown outside in the south-western or other sheltered and warmer districts.

NAMES OF PLANTS.—S. M.—1. *Mesembryanthemum conspurcans*; 2. *Crassula* sp. (please send when in flower); 3. *Mesembryanthemum muricatum*.—M. O. S., Mon.—*Juniperus chinensis*.—G. H. W.—1. *Tamara tetrandra*; 2. *Crataegus Carrierei*.

It's a great feeling—

to have worked hard on the garden and to be covered from head to foot with it! The soil seems to fit as comfortably as a suit of old clothes.

But there's something better still—to be pleasantly clean again when the job is finished. If the signs of honest toil stay on too long they get into the pores of the skin and you feel "stuffy."

KIT will get them out. And not only dirt as thick as you please, but the heaviest blobs of paint, grease or tar. KIT is the magic mover of all things that stick to the skin—the rub-and-a-wipe-and-it's-over soap.

**The "PERFECTOR" ARCH** forms an ideal setting for the Rose Garden. The man whose pride is in his Garden will appreciate the simplicity and effectiveness of this design. The construction is light, yet strong enough for a permanency, being specially designed for the cultivation of climbing Roses, Clematis, etc. It is made entirely of OAK and treated with Solignum, size 7 ft. high above ground level, and 3 ft. 4 in. wide inside. **Price £1 each.** Orders for three or more will be sent Carriage Paid. Cash with order. These can be made wider than 3 ft. 4 in. if required, prices for which will be quoted on application, stating number required.**THE
"PERFECTOR" PERGOLA.**

This is constructed with the above Arches spaced any distance up to 6 ft. apart. The longitudinal and secondary cross bars to complete the Pergola are supplied in OAK, treated with Solignum, at 1/6 per foot run of Pergola; any lengths to suit your requirements. Thus the price of the Pergola illustrated 25 ft. long, works out as follows:—

4 Arches at £1 each ..	£4 0 0
25 ft. run Top Bar at 1/6 ..	£1 17 6

NICOTINE! NICOTINE! NICOTINE!

No Compound, poisonous or non-poisonous, is as effective or as safe as English-made Nicotine for destroying all sucking insects infesting vegetation. It cannot be bought in a more convenient form for spraying or syringing than as—

CAMPBELL'S NICO SOAP (Nicotine Soap). The best Potash Soft Soap plus 7½ per cent. Nicotine. A teaspoonful will make one gallon of strong spray fluid. Prices:—½ lb., 2/-; 1 lb., 4/-; 10 lb., 32/-.

CAMPBELL'S ENGLISH NICOTINE, 95-98 per cent. This is offered to large users or others preferring to make up their own fumigating and spraying compounds. Prices on application.

CAMPBELL'S NICOTINE VAPORISING COMPOUND. Nicotine content, 50 per cent. Prices:—10z., 1/6; 4oz., 3/9; 8oz., 7/6; ½ pint, 9/-; 1 pint, 17/6; ½ gallon, 61/-.

CAMPBELL'S NICOTINE FUMIGATING ROLLS, very simple and effective. In four sizes for 500, 1,000, 2,000 and 3,000 cubic feet. Prices:—7d., 10d., 1/6 and 2/- each.

CAMPBELL'S PATENT SULPHUR VAPORISER. The best method of exterminating Mildew from plants in greenhouses. In two sizes, for 5,000 and 10,000 cubic feet. Prices:—18/- and 20/- each.

Obtainable from Seedsmen, or, in case of difficulty, direct from the Manufacturer—

J. D. CAMPBELL, Nicotine Manufacturer,
5, LUND STREET, CORNBROOK, MANCHESTER.

"Auto-Shreds" did it!

I just burnt them on the ground and they thoroughly fumigated my plants. The judge wanted the name of the stuff that kept my flowers so insect-free. I told him "DARLINGTON'S AUTO-SHREDS." At all seedmen they cost:
No. 1. (To fumigate 10,000 cubic feet.) For tender or ordinary plants, 6/-
No. 2. (10,000 c.f.) Ordinary plants, 4/6
No. 3. (1,000 c.f.) Ordinary or tender plants, 1/-
No. 4. (2,500 c.f.) do. 1/9
W. DARLINGTON & SONS, LTD.,
HACKNEY, LONDON, E.8.

NOW READY.

Nearly 250 pages, with Index. Over 40 Illustrations and 8 Coloured Plates.

THE PRIMULAS OF EUROPE

With Botanical Classification, Descriptions, and Cultural Instructions

By JOHN MACWATT, M.B.

Crown 8vo., Cloth, 12/6 net; Postage 9d. extra.

The aim of the author has been to produce a handbook that will assist in the identification of those species of the genus *Primula* which are native to the European continent, and at the same time furnish practical guidance to the cultivation of such of them as have been introduced to our gardens where conditions differ so widely from those prevailing in their natural habitats.

Dr. MACWATT is an acknowledged authority on *Primulas*, and his book presents in a concise and interesting manner the results of many years of close personal observation and experience.

Published at the Offices of "COUNTRY LIFE," LTD., 20, Tavistock St., Covent Garden, London, W.C.2.

Notes from Maidstone.

STRAWBERRIES.

The increased rainfall
of the past twelve
months has greatly
benefited these plants.
Our beds this year have
never looked better, and
the crop of fruit, given
some sun, will be phe-
nomenal. We shall hope,
therefore, to be able to
supply vigorous runners
in the autumn, and are
now booking orders for
early delivery.

A Perfect Spray

The most economical and effi-
cient type of hand sprayer for
all plants and flowers is the Abol.
It gives a strong spray, which
may be varied from fine to medium
or coarse, as desired.

Abol Patent Syringes embody
the finest materials and workman-
ship. Many of them have been
in use for over 20 years.

Full particulars, together with
an interesting book on Garden
Pests, will be sent to anyone, gratis
and post free.

Abol Patent Syringes are specially
recommended by the National
Rose Society.

SOME CLEMATIS SPECIES

WHILE it must at once be admitted that for brilliant effect in the garden the species do not rival the large-flowered hybrids, a considerable number of them are attractive and useful hardy climbers. For pleasure-ground planting and the outskirts of woodland the species of *Clematis* should receive more attention. To copy nature, plant the stronger growers against trees and shrubs or at the foot of rough hedges over which they can ramble. In this case give the plants a good start by trenching a 3ft. ring of ground, and support them with stout stakes for the first year or two to prevent damage by the swaying of the branches up which it is intended they should climb. The Holly, the Yew and the Evergreen Oak (*Quercus Ilex*) are excellent "host" trees for the strong-growing Clematises. They are also useful, of course, for draping walls, fences and arbours. What to do with the butts of large trees after they are sawn from the trunks is by no means an uncommon question. In some instances the difficulty can be solved by turning them over on to the sawn surface and covering with Clematises.

While botanists have described more than 200 species of herbaceous, sub-shrubby and woody Clematises, not more than about twenty hardy climbers are worthy of considerable attention among the species. These are natives of Europe, North America and Asia.

C. MONTANA, the Mountain Clematis of the Himalayas, was first introduced in 1831. I give it pride of place among the species because of its free and rampant growth in British gardens. It is, no doubt, a very well known climber, but one worth planting in ten times larger numbers to clothe the bare walls of tall buildings, to cover arbours and summer-houses with masses of its pure

white flowers in May and to hang like a screen or curtain along the veranda and from the bungalow roof. Mr. Wilson introduced a summer-flowering form from China which has been named var. *Wilsoni*. Several varietal names have been given to selected seedlings with larger flowers, such as *grandiflora* and *superba*.

C. montana var. *rubens* I should place in a list of the twelve most valuable garden plants introduced from China by Mr. Wilson. He found it during his first Veitchian expedition of 1900. The purplish hue of the foliage, with reddish leaf-stalks and young stems and rosy red blossoms, at once attracted attention. It is as vigorous and, if anything, flowers more freely than the typical *C. montana*.

The flowers of *C. montana* and varieties are produced on the previous summer's growths, hence whatever pruning is necessary owing to its position should be done immediately after flowering. When growing at will over tree-tops, arbours, etc., little, if any, cutting is called for.

To explain one very useful position I may be pardoned for introducing a personal episode, though climbers other than the one mentioned would do equally well. Our house was a new one and my

father would not allow nails to be driven in the wall. He planted *Vitis inconstans* (*Ampelopsis Veitchii*). The stack-pipes were not fixed close to the wall and appealed to me as a position for a treasured seedling *Clematis montana* I had raised; it soon reached the top. Twenty-five years have passed, it is still there, and I am hoping now to visit the old home and prune my seedling as I have done many times in the interval of years.

C. ORIENTALIS.—This is the oldest member of a group of yellow-flowered climbers, natives of the Caucasus, Persia, Manchuria, North China and the Himalayas. The best known is *C. tangutica* from Central Asia, a very beautiful climber with rich yellow blossoms followed by globular, fluffy white clusters of feathered styles. The variety *orbicula* has attracted attention of late at several shows of the Royal Horticultural Society. *C. akebioides* is a form introduced rather more than twenty years ago by Mr. Wilson. In addition to small botanical differences our plants are more vigorous than the type and have darker yellow blossoms which continue to expand until late autumn with fluffy seed appendages through the winter. The long trailing shoots, which may grow up to 20ft. or more, should be pruned from

youth upwards, or the ultimate result is a few long bare stems and a heavy top.

C. FLAMMULA.—This deliciously fragrant species was first introduced to our gardens from Southern Europe in 1596. If restricted to one species this would be my choice, because of its Hawthorn-like fragrance, free growth and its season of flowering—August to October. Growing 15ft. or more in height, it is, however, not a plant one can closely train to a wall or fence, so that this Virgin's Bower must be allowed to ramble at will over porches, arbours and verandas. Against a wall or fence place rustic poles for support. Trailing

ONE OF THE MOST BEAUTIFUL OF NEW CLIMBERS, CLEMATIS MONTANA RUBENS.

The rosy blossoms have a setting of reddish purple foliage.

C. Yew, etc.—Blossoms against an ivy-covered wall or the frame of a house—creamy white blossoms—new to great advantage against the dark back—red. The flowers are produced on the shoots of the current year, so that pruning, which should be fairly liberal, is best done in February. Being inclined to become leggy and bare of shoots at the base, juvenile plants should be stopped fairly frequently to provide a good foundation for subsequent years.

C. rubromarginata is a hybrid between *C. Flammula* and *C. Viticella*. The flowers are white, heavily margined with reddish violet, and inherit the delicious fragrance of *C. Flammula*. A most valuable late summer and autumn flowering climber.

C. ALPINA.—Because of the petal-like organs between the sepals and stamens this species was formerly kept by Linnaeus in a distinct genus under the name *Atragene alpina*. It was first introduced to Britain in 1792, and is a native of North Europe, the mountains of Central and South Europe and North Asia. The plant is a slender woody climber with stems up to 8ft. or 10ft. long. The leaves consist of nine leaflets arranged in threes. The solitary nodding blossoms are bluish violet produced during April and May. In our uncertain climate this is a season when we may expect frosts, so that the Alpine Clematis should be planted in a fairly sheltered position. It is readily raised from seeds.

To the *Atragene* section also belongs the dainty Clematis *macropetala*, introduced from Kansu by the late Mr. Reginald Farrer in 1914. The blue-coloured blossoms have white centres

composed of numbers of petal-like segments, the flowers suggesting those of an *Aquilegia*. The normal flowering season appears to be from about mid-June onwards, though plants we grew in pots in a cold frame blossomed during April. This points to the plant being a useful climber for the indicated greenhouse.

C. CHRYSOCOMA.—This is a species from Yunnan (China), first introduced to France by the Abbe Delavay in 1884. It is a plant which requires some nursing and attention unless we garden in the favourable climate of the south and west, though I remember reading in *THE GARDEN* of it doing well with Mr. A. K. Bulley in his rockery at Ness in Cheshire. It is a plant for the warm west wall trailing up among a few pea-sticks 3ft. or 4ft. high; young shoots push up each year from the base. In Cornwall I am told it grows taller. The creamy flowers are tinged with pink.

A hybrid *C. chrysocoma* × *C. montana rubens* named *C. verticillata*, raised at Verrieres et Bursson by Messrs. Vilmorin, is a valuable addition to hardy climbers. In freedom of growth the hybrid favours the male parent. The glistening rose-coloured blossoms are freely borne in May and June.

Another Chinese Clematis of recent introduction is *C. FARGESII*. It has satiny white blossoms 2ins. to 2½ins. across, and its flowering season is quite a long one—June to September. The plant suggests in some respects a summer-flowering *C. montana*, so that it is a useful climber for verandas and porches.

C. VITICELLA.—This South European species is one of the parents of many garden Clematises.

The average height is about 10ft. or 12ft. The blossoms are freely produced from July to September, and are 1½ins. to 2ins. across. The colours vary from mauve to blue, purple, rosy purple, reddish purple and white. This Clematis is not so woody in growth as some species, the ends of the shoots dying back for a length of 2ft. or 3ft. in winter. This does not matter, as the flowers are produced on the young growths of the year and, in any case, fairly hard pruning is necessary.

C. PANICULATA. This species was introduced from Japan, and is said to be also a native of China. It is vigorous in growth, and flowers freely in autumn after a hot summer, such as that of 1921, when our plants were covered with white blossoms about 1in. across. A hawthorn-like fragrance is pleasing. Prune freely in February or March if the plants have covered the allotted span.

C. REHDERIANA.—This free-growing Clematis from Western China was first introduced to France in 1898. Kew received a plant from M. Lemoine in 1904 under the name of *C. Buchaniana*. Mr. Wilson introduced the same plant in 1908, and it was named *C. nutans*. Subsequent investigations proved that the Chinese plants were distinct from these two species, which are both Himalayan. Hence the name *C. Rehderiana* was given by Mr. Craib to the subject of this note, which is a very distinct autumn-flowering climber. Vigorous in habit, it will grow up to 20ft. or more in height, producing in autumn a wealth of primrose yellow blossoms which are notable for their cowslip-like fragrance. *C. Veitchiana* is a form or variety of *C. Rehderiana* with doubly pinnate leaves.

CLEMATIS FLORIDA, VAR. BICOLOR, BETTER KNOWN AS *C. SIEBOLDII*.
Petals white, centre of flower purple.

THE INVALUABLE CLEMATIS MONTANA.
Perhaps the best known, as it is the easiest to grow, of Clematis species.

C. COCCINEA.—A native of Texas, this species is rather tender and requires the shelter of a wall at Kew. It has reddish scarlet pitcher-shaped blossoms, which the hybridist has used to some extent in the raising of several garden sorts, notably Countess of Onslow. The flowering season is late summer and autumn.

In addition to the purely garden Clematises a number of hybrids have been raised which, in addition to their decorative value, are of some scientific or botanic interest. *C. Hendersonii* is a hybrid between *C. Vitiellae* and *C. integrifolia*, producing rich bluish purple blossoms in summer and autumn. *C. Jouiniana* is a most useful autumn-flowering climber with bluish white blossoms. The parents are *C. Vitalba* and *C. Davidiana*. *C. Durandii* is another *C. integrifolia* hybrid with bluish purple flowers.

THE SUB-SHRUBBY CLEMATISES are very showy plants for shrubbery and mixed flower border. *C. tubulosa* (*C. heracleifolia* of some gardens) is one of the best known, growing about 3 ft. high and having deep blue flowers freely borne on the herbaceous stems in late summer and autumn. This group we usually cut to the ground in spring, though on a wall or fence *C. Davidiana* becomes more woody and climbs to a height of 8 ft. or more against 4 ft. or 5 ft. in the open. *C. stans* is a native of Japan and has pale blue or almost white flowers. Though dying back nearly or quite to the ground in some winters, it will make shoots 5 ft. to 6 ft. long in one season. *C. Lavalleyi* is another of this group notable for its vigorous growth and long inflorescences, though they are not so large and rich in colour as *C. Davidiana*. A. O.

THE BEST HARDY GERANIUMS

For Border or Woodland.

WHY the hardy Geraniums are not more often grown it is difficult to understand, for here is a race of plants consisting of many kinds of superlative merit for border and woodland. Most of them are absolutely hardy, they are not fastidious as to soil, propagation is comparatively easy, practically all are perennial and long-lived, and they are most reliable and abundant bloomers.

In considering a few of the more notable of these, omitting those usually grown in the rock garden, a good word may first be put in for the old *G. grandiflorum*, an excellent species for a cool, half-shady place which it may be allowed to cover with its handsome foliage and big blue flowers. Though it will thrive with full exposure, the blossoms of *G. grandiflorum* are inclined to appear a purple colour in direct sunlight, when their season is also more brief than it is under cooler conditions. Near to this comes the taller *G. ibericum*, with its copious heads of rich violet-purple, darkly veined blossoms. This is a plant that is much improved by good feeding, though it likes a dry, warm spot. Its one failing is that its flowering season is short, but it makes up for this by assuming brilliant leaf tints in autumn. So much may also be said of the somewhat similar *G. gymnocaulon*, which has bluer flowers; but both of these apparently allied Eastern species are apt to vary considerably in colour and habit.

Like the above, *G. armenum* is herbaceous, but it is much larger, its long, branching stems and deeply cut leaves covering a couple of square yards by early July. This mound of green then breaks into innumerable flower-heads, the blossoms, which open usually in pairs, being about 1½ ins. across and of an intense blood crimson. To some eyes there is more than a suggestion of magenta in these gorgeous blooms, but while this may be most apparent when the latter are fading, the jet black centre and veining are sufficient to tone down and refine any special virulence the colour of the petals may possess. In any event none but the ultra-squeamish would do other than welcome to the garden such a remarkable plant as this, but those who are discreet will, naturally, allow it plenty of greenery for background.

The Madeiran *G. anemonæfolium* is unique among its kind and, to my mind, quite the handsomest of the taller ones in cultivation. Though it has been known to us for over a century, this plant is still rare, possibly because it is not deemed perfectly hardy. Nevertheless, since it will endure tolerably keen frosts, put up with excessive

wet and other miseries, and yet bloom heartily from early June until the end of July, it is a species that one feels justified in including in any such

two upper petals narrower than the three lower ones as in some *Erodiums* and *Pelargoniums*. This admirable plant is easily raised from seeds and always comes true, and in many gardens self-sown seedlings are of quite common occurrence.

If one were to place *G. anemonæfolium* at the head of a selection chosen for any locality of moderate climate, *G. Wallichianum* could put up a good claim for that position as an all-round, hardy species. Here, however, we have another old plant that is not so well known as it ought to be, but even though one may suspect it of tenderness, since it comes from Nepal, it appears to be able to withstand any amount of frost. In any case, it being quite deciduous, there would be no difficulty in protecting its thick, carrot roots with a covering of ashes or litter where the climate is uncommonly severe. As, however, this was not found necessary even in the early part of 1917, when not a single plant here was injured, *G. Wallichianum* may, I think, be accounted safe enough for general use. This species is not less distinct in its own way than the foregoing, since it is a semi-trailer and one of the few of its race which enjoy a cool corner, where only morning or evening sun comes. A well grown plant will cover several square feet with its tangle of ruddy

THE ROSY GERANIUM ENDRESSI WITH *SENECIO CLIVORUM*.

list as this one. This magnificent species makes a luxuriant, tufty growth of large, fleshy leaves, deeply cut and glossy, not unlike those of the Water Hemlock, which rise stiffly from a short, woody stalk. The leaf-stems, and those of the flowers which rise clear of the leaves to some 2 ft. to 3 ft. in height, are covered with iridescent hairs. As to the blossoms, which are borne in clusters at the tips of these many-branched stems, these open in couples, and they are of a most exquisite clear satiny rose which glows to a vivid ruby at the eye. From the latter protrudes a prominent wisp of stamens of its own gleaming hue, and these are rendered the more conspicuous owing to the petals opening almost flat. These petals, which are without any veining, do not overlap, as do those of most other Geraniums mentioned here, the flowers being starred and the

stems and grey green leaves, and this mass of growth will bear from mid-July to autumn a prolific crop of blossom. In the best form of this species, viz., E. C. Buxton's Variety, these flowers are an untarnished azure with a large central zone of white and, being saucer-shaped and about 1 in. across, they bear a close resemblance to those of *Nemophila insignis*. These flowers are infinitely superior to the lavender purple ones of the type, the variety will come fairly true to colour from seed, and if care be taken regularly to weed out all but the bluest forms, one may preserve the purity of the strain indefinitely.

G. collinum, if my identity fails not, is also a semi-prostrate species of about 1 ft. in height, with deeply divided leaves of a more grassy green than most and pairs of blood crimson flowers

in July, these being about 2 in. in diameter. Of somewhat similar habit, but with a more, less straggling growth, is the new comer, *G. Russell Prichard*. This is said to be a hybrid between *G. Endressii* and *Fraversii*, and must be considered one of the most valuable of recent additions to this family. Though one may at once detect the influence of *G. Fraversii* in the beautiful silky and silvery leaves and stems of this variety, it is not so easy to guess where *Endressii* comes in, for while the flowers of the hybrid are of a most sumptuous and intense velvety crimson, those of the best forms of *Fraversii* can hardly boast of anything stronger than a clear rose, and *Endressii*'s pink, full as it may be, is subdued by a chalkiness of the raspberry-like description. *Albert G. Russell Prichard* is a glorious thing, one that will win distinction on sheer merit in the gayest of June's gardens.

G. Traversii, the New Zealander, I need hardly add to what has been said, is an exceedingly choice species, none too robust save in well drained, warm soils, and the only one of the larger *Geranium* species in common use which has really silvery leaves. There are many forms of *G. Traversii* with both large and comparatively of one goes by the foliage; small blossoms, and these may vary from white through various degrees of blush to a fresh rose. *G. Endressii* alone is well worth a place in any garden. But feeble and mild as it may appear, *G. striatum* must not come within a mile of *Endressii* or the two will people the earth with their half-caste offspring and pass on to this Pink Peril a zest for colouring which seems to increase in intensity in direct ratio to the swarming increase of the redundant hordes.

Garden forms of *G. sanguineum* must be included in this selection, for few of these are other than first-rate for sun-beaten banks or the foreground of dry borders, where they will cheerfully maintain a long succession of these fiercely magenta-crimson flowers, which have earned for the native type the name of Bloody Cranesbill. The white form, or sub-species, known as *G. s. alba*, is a really choice plant, bigger and bushier than the crimson with leaves of a darker green and abundant blossom of a chaste and delicate beauty. *G. nepalensis* of the trade is, I rather think, not the rightful owner of that name, but a glorified form of *sanguineum* and of which the larger flowers are certainly no less gaudy. As for *G. lanceastrum* and *nodosum*, the only excuse one has to offer for including such a dwarf as the former in this list is its undeniable sweetness and charm and its supposed relationship with *sanguineum*; and the rather larger *nodosum* slinks into the company on the strength of the fact that, since it interbreeds so blatantly with the *G. sanguineum*, a few seasons' intercourse between the two will yield a tribe of intermediate forms which blazon every degree of "bloodness" which it is possible to conceive. However, none of these, species or hybrids, deserve to be called harsh in colouring; their foliage is very lovely at this season and again in autumn and, as I have said, they will often live happily where a House Leek would suffer thirst.

The last group which claims mention here is that of *G. pratense*, the 2 ft. to 3 ft. native, so well known in old cottage gardens. Of this species the best forms are the pure white and pale blue singles, the heavy old plants for open woodland spaces, both of them appearing to best advantage in partial shade. So much may also be said of the rarer double blue (not the common double in that colour), which is a really handsome plant, growing in cool, good soil up to nearly 4 ft. and bearing a generous and successional crop of good-sized blossoms in a clear smoke blue which is very appealing, especially in evening light. N. WATTS.

SHRUBS OF A MIDSUMMER GARDEN

A GARDENER should, perhaps, not expect to wring much encouragement out of an almanac, but I confess to a sudden spasm of hopefulness which thawed my coagulated soul a few days ago when I came across the statement, "June 21: Summer Commences." That at least inspired me with the feeling that there was still time for this dismal season to make amends for its inclemency. And with that consolation to cheer one on, the outlook might have taken a brighter turn had not that very same almanac, on the self-same page, cast one's illusions into the abyss by blandly remarking, "June 24: Midsummer

Fuegias and Solanums point to a soil that is warm and congenial to root action.

Among the above *Fremontia californica* is now perhaps the proudest shrub in the garden, its somewhat stilly radiating branches blazing with the big, golden, orange-centred flowers, which are of so leathery a texture that they are able to defy the rough and chilly winds. *Solanum crispum* also has never been better. Though its blue-purple flowers are a paler hue than usual, this gradually improves with the advancing season, the form known as *S. c. autumnalis* being of a particularly rich colour later on. *Sollya heterophylla*, a twining shrub from Australia, is very

charming on a south wall, its myrtle green foliage being strung with dainty little bell-flowers in a clear violet-blue, swinging on elegant hair-like pedicels from the leaf-axils.

Of a good many Clematises *C. Henryi* has long ago won for itself a place of high appreciation here, not only because it is still one of the handsomest of its kind, but because it is such a hearty grower and perennial blossomer. We have it both on a wall and covering an ivy-clad, decapitated Oak tree, and in both situations it opens its enormous white flowers as soon as those of the montana class have gone off and continues to provide us with an unbroken succession until autumn. Lady Northcliffe is very lovely on a similar kind of stump, but with Golden Hop instead of Ivy for company, and

THE BEAUTIFUL AND LONG-FLOWERING ST. DABEOC'S HEATH,
DABOECIA POLIFOLIA.

Day." I do not know whether our learned chronologists often amuse themselves with that form of humour and, happily, it does not matter. I metaphorically rubbed in some whale oil and penetrated the outer gloom to see how the flowers were faring.

If one confesses the truth, however, it has not been so much the flowers as ourselves which have done the grumbling during the last six weeks. The former hardly ever looked better than they do now and the earlier ones have seldom had so long a season, the explanation being that in a normal season sunshine and rapid evaporation combined are with us in excess of the rainfall. This time the plants in our sharply drained, porous soil have had all the moisture they need, while the sunshine, if niggardly to us, has been ample for their needs. Had the winter been cold and severe and the spring late, another tale might have been told; but the splendid growths which one sees to-day on such heat-loving plants as *Romneyas*, *Fremontias*, *Dendromecons*,

another variety which has proved to be extraordinarily floriferous and long-lived is *Comtesse de Bouchaud*. The satiny rose blossoms of this fine old Clematis are produced in abundant masses from June to the end of August and sometimes well into autumn.

Comparisons may be especially odious when it comes to Cistuses, for they are all lovely. But if I ever were doomed to grow but one variety, I think my chosen idol would be *C. immaculatus*, an unblotched variety of *C. ladaniferus*. Immaculate indeed are the very large blossoms of this beautiful shrub, and never are they so chaste and refined as when one happens to catch them at that rare moment when the half-opened flower is unfolding its spotless purity of its petals and yielding its delicate creases to the gentle warmth of an early sun.

All winds, again, are not without their virtues among the Cistuses, for in dull, cool weather one can often enjoy a full display of blossoms until late afternoon. *Cistus Gauntlettii*, which

might be described as a fuller-toned Sunset, with a more robust habit and an amazing prolificacy, retains its gorgeous flowers longer than most, and a colony of *C. obtusifolius*, which only gets morning sun, being overhung by Oaks, will often preserve its pure white, yellow-based petals until late evening or the following morning. Both *C. (Helianthemum) formosus* and *C. f. unicolor* are much more punctilious. No eight-hour day is tolerated in their union, and such artful machinations as "summer-time" they scorn. Even so, we love them not the less but probably more for the brevity of their morning hour, and they are still without a rival in their class.

Yet another plant which has shewn its appreciation of cool conditions is *Menziesia (Dabecia) polifolia*, the young flowering growths being finer and more abundant than we have seen them for a long while. The rosy purple blossoms of this type, moreover, have not suffered from that sun-bleaching which so often mars their really good colour, and both these and those of the lovely white form are unusually large and full in the bell. These and other forms of the same thing may be said to open the season of the summer Heaths, but *E. cinerea* runs them close. Of this latter the variety *rosea* is perhaps the best for all-round use, and its abundant flowers in a full, yet soft rose are very charming. *E. c. atropurpurea* is another admirable variety in a deeper, more crimson shade, and, not to be overlooked, is the quite dwarf but very brilliant *E. c. coccinea* with bronzy foliage and little bells of a dazzling crimson-lake.

Among other things now in bloom on the Heath slope are some *Helianthemums*, mainly a grey-leaved, yellow variety, much like the common wild species greatly enlarged, *H. humulatum* and the trailing *H. polifolium roseum*, a very easy and free grower with flowers of a pale salmon-buff shading to rosy orange at the centre. A very sunny corner of thin soil is now gay and fragrant with Wild Thyme, another impoverished place is the happy home of the double form of the common Bird's-foot Trefoil mingled with the white foam of *Galium saxatile* (Heath Bedstraw), and there are some groups of *Linum perenne*, whose sheeny turquoise blossoms on their elegant stems are not less delightful among Heathers than are the Harebells of later days. *Genista sagittalis* is also here, covering its unkempt foliage with woolly heads of yellow flowers. *G. germanica* is rather more successful in winning one's admiration than is *saxatilis*, but neither are quite so appealing as the rather humble little *G. dalmatica*, with its delicate, pea-green foliage and bright yellow spikes of bloom. All of these and others will have to give place, however, before the month is out, to the dazzling glory of *G. tinctoria flore pleno*, which will transform its spreading mass of glossy dark green foliage into a blaze of brilliant gold.

Where cooler conditions prevail *Gaultheria trichophylla* is concealing its china blue berries, big as robin's eggs, beneath its pretty foliage, and here also one welcomes the handsome leaves and tall white spires of *Galax aphylla*, a prince among woodland plants. *Zenobia speciosa* is in this select company, its branches hung with milk-white urns, and there are one or two others of the same class of shrub which, however, do not seem to prosper quite so well in the absence of peat and natural moisture. Their ally, *Kalmia latifolia*, however, is perfectly content, and this is always a precious shrub in any of its forms, which vary from pale blush to pink.

Escallonia macrantha is a fine shrub where it does well, the best of the early flowerers of its race and one that will bloom almost throughout the season. Here it is quite hardy enough to make

a bush 8ft. to 10ft. high in open spaces in the woodland, and not only is its glossy foliage as sweet as a Balsam Poplar, but the large sprays of flowers, so liberally yielded, are a bold ruby crimson, just escaping that heavy, Victoria Plum red which is characteristic of not a few Chilean shrubs. As soon as it gets leggy *L. macrantha* should be cut

back to near the ground, the result being finer foliage and larger and better blooms. *E. exoniensis* is another early and very worthy member of this group, producing an abundant crop of rose-tinted, creamy white flowers of a waxy texture which have an admirable background in the deep green of the highly burnished leaves. A. T. J.

THE SOUTH SEA MYRTLES

THESE are not many really choice New Zealand flowering shrubs that can be grown generally in all the milder parts of this country, but the subjects of this note, the various members of the *Leptospermum* family—afford a notable exception. Though not strictly hardy, the *Leptospermums* will, as suggested, prosper as unprotected bushes almost anywhere on or near our west and south coasts, and in much severer climates they will do admirably against a wall or fence. A light, free soil is, however, desirable with full sun and as much shelter from cutting winds as may be. Perhaps the best known of the South Sea Myrtles is *L. bullatum*, whose small, glossy green leaves, which grow so densely on the slender whippy growths, are almost hidden from view in the later spring by the multitudes of pure white flowers. These latter are about the same size and shape as those of the common Hawthorn,

and they have dark centres which serve to intensify their milky whiteness. *L. scoparium* is, according to some, synonymous with the above, but not a few nurseries list a pale blue lilac form under that name.

L. s. Nichollii is an even more attractive bush whose similar leathery foliage is suffused with a warm plum red. In this variety the flowers are a rich blood crimson, the opening buds being a brilliant ruby. *L. Chapmanii* might be said to come between the foregoing with rosy crimson flowers; then there is *L. stellatum*, whose elegant growths become starred with white flowers rather smaller than those of the above. *L. L. levigatum* and *lanigerum* also have white blossoms on a glaucous and silvery (hairy) foliage respectively. Yet another notable member of the genus is *L. Boscawenii*, whose foliage is slightly tinted with a ruddy bronze, the large pale blush flowers having a deep crimson eye.

In addition to these, several pretty hybrids, some of them of distinct merit, have recently been introduced. A prostrate form has appeared, and the near future will doubtless produce not only fresh novelties, but a greatly increased and deserving popularity for this interesting race. The blooming season of the various *Leptospermums* may be said to extend throughout the summer. Propagation of most kinds may be carried out by seed, which germinates readily, self-sown seedlings being by no means uncommon. Cuttings may also be struck without difficulty in the late summer. In either case growth is rapid under congenial conditions, and the plants begin to bloom when a foot or so in height. Though 4ft. to 6ft. may be considered the average stature of most of the *Leptospermums*, some kinds attain far greater heights in the south-west.

P. L. N.

THE BLuish LILAC LEPTOSPERMUM SCOPARIUM NYMEN'S VARIETY.

THE GREAT SUMMER ROSE SHOW

THE Summer Show of the National Rose Society must be classed as a great triumph for the management and the exhibitors over most adverse circumstances. Even those of us who can recall more seasons than we sometimes care to, cannot remember one which was so unkind towards flowering plants and especially to Roses. Following a mild winter the spring has been very backward and, except for a very few fleeting glimpses, we have, as yet, had no summer. To have blooms of the quality associated with the great summer Feast of Roses at Regent's Park a fortnight's real summery weather was required, and that weather consistently failed to materialise.

The adverse conditions have been so general throughout the country that over a week ago it was fully evident that the exhibits could not possibly be up to the standard of the Society. The Council met and seriously considered the question of postponing the Show for ten days or so, but the arrangements were so far advanced as to present serious if not insuperable obstacles to any attempt at abandonment. So it was decided, and wisely as matters have turned out, to continue as per plan and hold the Show. There were, naturally, gaps in the tents. The blooms were not of the superb quality of the past two or three years, but there were sufficient blooms of all types to make it a successful Show, and the quality was decidedly higher than was anticipated. On every hand one heard some such remark as "A week ago I could not have cut a

handful of Roses and did not expect to be able to set up a single stand," but these gloomy forebodings were far from being justified. Early in the day nearly all the Roses were distinctly in the bud state, and even at noon, when Queen Alexandra and Princess Victoria visited the Show, the blooms had not developed a great deal, but during the afternoon, under the influence of the warm weather which favoured the Show, the blooms opened out well, which made a wonderful difference to the appearance of the exhibits. Those who came even long distances to the Show had no reason to be dissatisfied, but owe a large debt of gratitude to Mr. Courtney Page, the untiring hon. secretary, and the exhibitors for providing what, in all the circumstances, was a really wonderful Show.

As ever, it was the new Roses that formed the first attraction, and throughout the live-long day there was a long queue outside the tent and, of course, a constant stream of members passing through. On the whole these new Roses were quite equal to the average at the Summer Show. The two gold medal varieties Bessie Chaplin and Lady Roundway were generally allowed to be worthy of that distinction, and the judges had not been influenced by the difficulties of the season in making the awards. With the certificated varieties, too, sentiment certainly did not appear to have entered into the matter. They all were particularly good varieties. It was pleasant to find that, besides being of good form and colouring, nearly all the new Roses were fragrant to a notice-

able extent. For some reason Mr. George Prince did not appear to have entered his basket of the new seedling Rose which was there named Victoria, but it had the old Damask Rose perfume and enraptured the few who discovered it. Princess Victoria was charmed with the flowers and their delightful fragrance and, to his great pleasure, permitted Mr. Prince to take the basket of blooms to Marlborough House.

The class for new Roses distributed during the past five years is nearly always disappointing, and one can only conclude that the raisers of gold medal Roses are too busy propagating them to have sufficiently good blooms for the Kibbee Stuart Cup. The cup was won by Mr. E. J. Hicks with a dozen moderate blooms. The best were Marjorie Bulkeley, Souv. de G. Remoya, Mrs. E. Hicks and Victor Teschendorff. Mr. G. Prince was second, and he had good blooms of Rev. F. Page-Roberts, Souv. de J. Pernet and Admiration. The class for twelve blooms of any new variety was decidedly better, and here Messrs. Alex. Dickson and Sons won the first prize with very good examples of Maud Cuming, the variety which received a certificate of merit. Messrs. B. R. Cant and Sons were a good second with brilliant blooms of Princess Victoria, and Mr. Hicks came third with Mrs. Henry Morse.

From the spectacular point of view it was the "Representative Groups of Roses" that were the feature of the Show, and although they were not equal to some former efforts, they were worthy of praise. Mr. E. J. Hicks had decidedly the

A LARGE AND SHAPELY HYBRID, MAUD CUMING.

THE GORGEOUSLY COLOURED LADY ROUNDWAY.

most successful group, and he won the Champion Cup, Gold Trophy and Edward Mawley Memorial Medal. The arches of Climbing Lady Hillingdon and Mrs. H. Stevens with tall pillars of Wichuraiana varieties in the background drew attention to the large stands of lovely blooms of Padre, Betty Uprichard, Chas. E. Shea, Hortulanus Budde, Golden Ophelia, Mrs. Henry Morse and many other excellent sorts. Messrs. B. R. Cant and Sons were second, and their best vases were of K. of K., Léontine Gervaise, Lemon Pillar, Emily Grey and Paul's Scarlet Climber. The Rev. J. H. Pemberton was third.

In the small groups Messrs. W. R. Chaplin Brothers, were awarded the first prize. They had plenty of blooms of very fine quality. The chief were Premier, Emma Wright, K. of K., Isobel, Ophelia and Mrs. C. E. Shea. The best roft. by 3ft. group was arranged by Mr. E. Easlea, who shewed Hoosier Beauty, Irish Fireflame, Ophelia, Melody, Henrietta and similar varieties. Mr. T. Edwards was second, and he had an excellent vase of Hortulanus Budde.

It was surprising to find so many exhibitors of seventy-two distinct blooms of exhibition Roses, and all were of quite fair quality. The Championship Trophy was won by Messrs. D. Prior and Son with a collection of even quality and a good distribution of colours. Perhaps the pinks predominated, and these included Mrs. Henry Morse, F. W. Dunlop, Mrs. G. H. Welch, Mrs. Charles Hunter and Lohengrin. Of the more brilliant colours Augustus Hartmann and Princess Victoria were very good indeed, while Modesty, Bessie Brown, Mrs. C. West and Mme. Melanie Soupert were also worthy of note. Messrs. B. R. Cant and Sons, who were second, had rather more reds, including E. Godfrey Brown, Captain F. Ball, C. V. Haworth, H. V. Machin and George Dickson; while their blooms of Gorgeous, Mrs. George Norwood and Mrs. Bryce Allen were also of good quality. Messrs. F. Cant and Co. were third.

There were no sets of three blooms each of thirty-six varieties, but there were some very good exhibits of forty-eight distinct blooms. Mr. George Prince won the China Trophy with quite a good collection which only lacked colour to have made it really excellent. His outstanding varieties were Mrs. Lamplough, Martha Drew, Modesty, Candeur Lyonnaise, Mrs. H. R. Darlington and Rev. Page-Roberts. Messrs. Jarman and Co., who were second, had rather more colour, their bright varieties being H. V. Machin, G. W. Forestier and A. Hartmann. Lady Ashtown and Ophelia were also good.

Messrs. Chaplin Brothers were alone in the class for twenty-four distinct varieties, where they were awarded the first prize for a good collection, but there were half a dozen sets of eight varieties, three blooms of each, and this was quite a good class. The prizewinners were Messrs. Jarman and Co., Mr. George Prince and Mr. Henry Drew in the order named. The chief varieties were C. V. Haworth, Mrs. Henry Morse, Mrs. E. Hicks, Hoosier Beauty, Media and White Maman Cochet.

Tea and Noisette Roses were surprisingly good, and Mr. George Prince won the first prize with a splendid eighteen blooms of such sorts as Lady Plymouth, Mrs. Foley Hobbs, Souv. de Pere Notting, Mrs. C. Hall and a beautifully coloured Auguste Comte. Mr. Henry Drew was second.

The baskets of cut Roses did not make the glorious display of last year, but by the middle of the afternoon, when the blooms had opened fully, they were much more attractive. The best Hybrid Teas were the new Maud Cuming exhibited by Messrs. Alex. Dickson and Sons in the new class and Hoosier Beauty by Mr. Prince in the

SEALING-WAX RED, THE BRILLIANT SINGLE ROSE
LITTLE JOE.

other. W. R. Smith, shewn by Mr. Henry Drew, was the best basket of Tea Roses. The baskets of decorative Roses, though also fewer, were as good or better than was expected. Messrs. Alex. Dickson and Sons, shewing K. of K., Sunstar and Betty Uprichard in good condition, were first with the seven, and Messrs. J. Prior and Sons won premier place with the three baskets. The collections of decorative Roses were very showy, and the Polyanthas were quite pretty. Ellen Poulsen, Coral Cluster, Alice Amos and Perle d'Or were the chief sorts in Mr. Prince's first prize collection.

The premier blooms in the trade classes were Candeur Lyonnaise (H.P.) shewn by Mr. George Prince; C. V. Haworth (H.T.) shewn by Messrs. F. Cant and Co.; and Lady Plymouth (T.) shewn by Mr. George Prince.

NEW ROSES.

Bessie Chaplin.—This was decidedly the finest Hybrid Tea Rose in the Show. The blooms were of perfect rounded shape, full in the centres with the outer petals beautifully disposed. The colour is a very pleasing silvery shell pink, occasionally slightly reddened on the outside, and the substantial broad petals are recurved. The buds are often of a shining rose cerise colour. The stems and foliage are perfect, and added to

these merits it is deliciously fragrant. Gold medal to Messrs. Chaplin Brothers, Limited.

Betty Hulton.—This appears to be a free-flowering variety which is of value for all decorative purposes. The shapely blooms are fairly large, and their colour is almost saffron yellow with an attractive sheen of gold. The blooms are sweetly scented. Shewn by Messrs. Alex. Dickson and Sons.

Gwynne Carr. A medium-sized, fully double Hybrid Tea Rose of deep shell pink colouring which becomes much paler as the blooms develop. It is a fragrant bloom and possesses long, stout stems. Certificate of merit to Messrs. Alex. Dickson and Sons.

Lady Roundway.—For glorious rich golden orange colouring there was no Rose in the Show to compare with this. The medium-sized, fully double blooms vibrated with warm colour and, being a Pernetiana seedling, the foliage is hard, but we must confess we thought it rather skimpy. It is said to be of bushy habit and perpetual flowering. That it is free-flowering was abundantly clear from the stems and plant which accompanied the stand of blooms. Gold medal to Messrs. B. R. Cant and Sons.

Little Joe.—This is a very uncommon single-flowered Hybrid Tea Rose. It is a medium-sized cupped bloom made up of usually five broad, substantial petals of sealing-wax red colouring with a small golden eye. The foliage is good. If it proves to be free-flowering, as we understand it is, it should be an exceedingly desirable garden Rose. It was raised by Mr. F. J. Looymans. Certificate of merit to Messrs. D. Prior and Son.

Maud Cuming.—The colouring of this handsome and large Hybrid Tea Rose is very baffling. The general colour impression is peach shot with coral pink, but there is also more than a suggestion of orange and the outer petals are delicately veined. It is, however, a fragrant and beautiful Rose, fully double and of globular shape. The bold shell-like outer petals and the general colouring remind one of a Peony. The foliage is good and the stems have comparatively few spines. Certificate of merit to Messrs. Alex. Dickson and Sons.

Shot Silk.—This appears to be a very free-flowering variety suitable for the garden and for house decoration. It is a fully double Hybrid Tea Rose of very uncommon orange rose colour heavily shot with golden yellow. The roundish petals are nicely recurved and it is very sweetly scented. The dark green foliage suggests Pernetiana parentage. Certificate of merit to Messrs. Alex. Dickson and Sons.

Vesuvius.—This is a practically single fairly large deep crimson maroon variety of which the blooms shewn were obviously not at their best. Even so it attracted a deal of attention. Shewn by Messrs. D. Prior and Son.

Further details of this Show are, for want of space, held over for our next issue.

DELPHINIUMS AND CAMPANULAS AT VINCENT SQUARE

THE stranger within our gates who on landing came straight to the Royal Horticultural Society's Hall on June 26 and 27, might well be excused if he concluded that Great Britain has been favoured with ideal weather throughout the spring. He would have found the hall filled with glorious flowers as perfect in form and as rich and varied in colouring as even the most critical would wish. There were so many groups that the Floral Committee recommended the award of forty-one medals, while the floral novelties placed before the Committee were so numerous as to make a show by themselves.

In quantity Sweet Peas and Delphiniums predominated, and they were of high quality, but even these must give place to the splendid *Salpiglossis* which were sent from the Society's garden at Wisley. These plants deservedly had the central position in the hall, and the large circular group made a memorable display. The delicate texture and beautiful colourings of this flower make a great appeal. While every possible shade and combination of colours were represented, yellow seemed to predominate, and this gave a most fascinating golden tone to the flowers. We understand that the plants had been grown in a cool greenhouse, and they were models of skilful cultivation. A gold medal, unanimously recommended, was a fitting honour for these splendid plants.

A second gold medal was awarded to Messrs. Sutton and Sons for a splendid collection of Sweet

Peas arranged in the charming manner that is characteristic of the Reading exhibits. The countless spikes of bloom were all of the highest exhibition quality, and a great many of the very best varieties were represented. Messrs. Dobbie and Co. also set up a fine collection of Sweet Peas which was second only to the foregoing. Besides many varieties already in commerce, they had several which are to be distributed next year. *Mary Rose* is a very attractive variety of deep pink shade and *Royal Sovereign* a rich orange yellow. *Youth* was shown on behalf of Messrs. C. C. Morse and Co., the famous Sweet Pea firm of California, and in this variety they have what "over there" is termed "a winner." The pictorial effect of the blush pink on the upper segments of the white flowers is particularly charming. In the annexe Messrs. Robert Bolton and Sons shewed in considerable quantity some of their novelties. *Daffodil* is well named. *Come Valley* is a desirable mauve variety, *Comrade* is beautifully tinted with pink, and *Wizard* a very fine deep orange-scarlet. Messrs. J. K. King of Coggeshall shewed a good selection of standard varieties in the body of the hall.

The Delphiniums shown by Messrs. Blackmore and Langdon were magnificent, and in their stately grandeur and lovely colouring shewed no signs of the unfavourable spring. Their two new sorts were displayed in quantity and, besides these *Queen Mary*, *Queen of Bath*, *King Bladud* and the *Alake* were excellent. Near by Messrs. R. H. Bath, Limited, had some splendid *Paeonies*.

The very large, fully double blush flowers of *Lady Carrington* excited a deal of envious admiration. *Edulis superba* is a lovely rich pink, and there were also several good *grandiflora* varieties. As a background Messrs. Bath had many good Delphiniums. A large number of *Promies*, both singles and doubles, were staged by Messrs. Kelway and Co., and these embraced many beautiful colours.

Chief among the other border flowers were *Roses* and *Pinks*, though the former were not nearly so numerous as at recent shows. Messrs. B. Ladham, Limited, had a great many very fragrant *Pinks*, and Mr. Charles Turner also had a good collection. *Pheasant's Eye*, *Aurora*, *Elsie*, *Charles Ladham*, *Glory* and *Florizel* are all very pretty. *Dianthus Pirebright Glory*, a free flowering prettily fringed and fragrant variety, is excellent for massing.

Messrs. John Harkness's exhibit of *Lupins* was crowded out into the orchid annexe, and indeed they almost rivalled *Orchids* in their range of colouring. This flower does indeed make progress!

Carter's *Island Poppies* *Crépe de Chine* were delightfully arranged, and shewed how useful they are for table decorations. *Campanula Felham Beauty* was very well shewn in several collections, and in addition Mr. F. G. Wood had several batches of the dwarf yellow *Mimulus Burnettii*.

The association of the brownish apricot spikes of *Verbascum Cotswold Gem* and *Cotswold Queen* with *Hesperis matronalis alba plena* in the group

THE BEAUTIFUL AZURE DELPHINIUM BLUE BOY.

DEEP HELO MAUVE DELPHINIUM UNIQUE.

of Messrs. R. Tucker and Sons was a particularly happy one.

Stove plants were represented by splendid specimens of *Dracena Lindenii* from Baron Schröder's gardens at The Dell, Englefield Green, and these were raised above a large quantity of brilliant plants of *Crassula coccinea minor*, all superbly grown. Messrs. L. R. Russell, Limited, had one of their famed collections of miscellaneous stove plants, among which those with ornamental foliage were very handsome. The Hon. Vicary Gibbs sent a very praiseworthy collection of *Streptocarpus*.

There was only one collection of Roses (no doubt the others were reserved for the Regent's Park Show) and only one set of blooms for the Clay Cup competition. Greenhouse Carnations were as numerous and as beautiful as ever, and Mr. James Douglas brought a collection of his magnificent Border Carnations almost as a sort of preliminary canter for the special show at the next meeting. On the present occasion the blooms were perfect in form and colouring.

Unfortunately, the first of the silver medals which Messrs. G. Bunyard and Co. are offering for various fruits shewn by amateurs did not bring any competition. On the present occasion the medal was offered for the best collection of Strawberries, and it was deservedly awarded to the only exhibit. Mrs. R. W. Ascroft, Orchard Cottage, Effingham, shewed four very good dishes of Royal Sovereign, which had a most refreshing aroma, and they were attractively set out with vases of Sweet Peas. At the next meeting a similar medal is offered for Cherries grown by an amateur.

Messrs. Barr and Sons exhibited a very good collection of seasonable vegetables of high quality. Cauliflowers, Lettuce, Turnips, Carrots, Broad Beans and Peas were the chief dishes.

NEW AND RARE PLANTS.

Campanula persicifolia gigantea Queen of June.—The name is very cumbersome, but can easily be shortened for everyday use. It is a very handsome variety, much of Telham Beauty type, and with its tender pale blue colour is a fitting companion to that popular variety. It is well worth an award of merit, but for some reason, best known to the majority, the Floral Committee passed it over. However, it was greatly admired by visitors. Shewn by Messrs. B. Ladhams, Limited.

Campanula The King.—A very ordinary cup-and-saucer *Campanula* of medium blue colour. Award of merit. Shewn by Messrs. B. Ladhams, Limited.

Carmichaelia flagelliformis.—In general appearance this New Zealand shrub is much like a *Notospartium*. It is a practically leafless shrub, making plenty of wiry shoots freely furnished with small, deep lilac coloured, pea-shaped flowers. It is moderately hardy, and interesting rather than beautiful. Exceptionally well flowered sprays were shewn by Lieutenant-Colonel Messell.

Delphinium Blue Boy.—This is a very long spike made up of medium-sized, star-shaped flowers of bright blue colour with a white eye. It is quite the best of its colour and type. Award of merit. Shewn by Messrs. Blackmore and Langdon.

Delphinium Mrs. Townley Parker.—A handsome, compact, well rounded spike of large single flowers of Cambridge blue colour with a small white eye. Award of merit. Shewn by Messrs. Blackmore and Langdon.

Delphinium Unique.—The name is quite appropriate, for it is a very remarkable *Delphinium*. The spikes are long, graceful and a trifle loosely furnished with medium-sized, perfectly round, semi-double flowers which have prettily waved reflexed margins. The colour is deep heliotrope mauve, and there is a small black eye. Award of merit. Shewn by Mr. T. Carile, Loddon Gardens, Twyford.

THE CURIOUS WEIGELA-LIKE KOLKWITZIA AMABILIS.

Kolkwitzia amabilis.—This uncommon hardy shrub is of somewhat spreading habit, and its flowers much resemble those of an *Abelia* or a *Weigela*, but it differs decidedly from either in its hairy stalks and calyx. The bell-shaped corollas are pinkish with yellow throats. The opposite leaves are broadly ovate and prominently veined. Award of merit. Shewn by Lieutenant-Colonel Messell.

Lilium Golden Orb.—A graceful, medium-sized variety of *Hansonii* type and, except that the flowers open quite flat, a deal like *L. Mrs. R. O. Backhouse*. The individual flowers are from 2½ ins. to 3 ins. across and the rich yellow colour is freely spotted with small crimson dots which are darker in colour towards the centre of the flower. Award of merit. Shewn by Messrs. Wallace and Co.

Lupinus Harkness' Regal Strain.—The award was given to a very beautiful strain of *Lupinus polyphyllus*. Many charming shades and combinations of colour were represented, and those of old gold and pink tones were especially delightful. Award of merit. Shewn by Messrs. John Harkness and Sons, Bedale.

Papaver Ethel Swete.—This new Oriental Poppy was shewn by three exhibitors. It is a very handsome, large flower of satiny pink colour and has a black centre. Award of merit. Shewn by Messrs. Barr and Sons, Messrs. Gibson and Co., and Messrs. Harkness and Sons.

Papaver Mrs. H. G. Stobart.—A very similar variety to the above but of rosy cerise colour. Both sorts are well worth growing. Award of merit. Shewn by Messrs. Barr and Sons, Messrs.

Gibson and Co., and Messrs. Harkness and Sons.

Cattleya Hentschellii Rosslyn Var.—A strikingly handsome stove Orchid. The large flowers are of royal purple colour. The large lip is attractively frilled and has an orange-yellow throat. Award of merit. Shewn by Mr. H. T. Pitt.

Lælio-Cattleya Mrs. Willoughby Pemberton The Dell Variety.—Three very large flowers were

shewn on a magnificent plant. The sepals and petals are of sparkling blush mauve, while the large, spreading, frilled lip is of rich crimson colour with a broad bar of golden yellow in the throat. It is a strikingly handsome variety. First-class certificate. Shewn by Baron Schröder.

Odontoglossum Ernest Bristow.—A medium-sized spike well furnished with roundish flowers. The sepals and petals are greenish yellow heavily marked with chocolate. The lip is freely and prettily spotted with lilac, which becomes deeper in tone towards the centre. Award of merit. Shewn by Messrs. Armstrong and Brown.

O. Orosius magnificum.—A handsome spike of large and shapely flowers. The bright chocolate sepals and petals are faintly tipped with very pale blush, while the lip is distinctly banded with milk white. A gold crest brightens the flowers. First-class certificate. Shewn by Messrs. J. and A. McBean.

FORTHCOMING EVENTS.

July 9.—United Horticultural Benefit and Provident Society's Meeting.—Bath Gardeners' Society's Meeting.

July 10.—Royal Horticultural Society's Fortnightly Meeting.—National Rose Society's Provincial Show at Saltaire (two days).—Jersey Gardeners' Society's Meeting.—Wolverhampton Floral Fête (three days).

July 11.—Ipswich and East of England Horticultural Society's Show.—National Sweet Pea Society's Show at Bath.—East Anglian Horticultural Society's Meeting.—Richmond (Surrey) Horticultural Society's Show.

CLOVER AS A LAWN PLANT

THAT white wild Clover has a remarkable faculty for withstanding drought, even on the poorest, driest and most sun-beaten of gravelly and sandy soils, is well known. That being so, one wonders why it is not more often used along with grass in the making or upkeep of such lawns as are liable to burn to a tawny brown before the summer is half over.

It may be urged that Clover does not wear as well as grass, that it is liable to cause slipping on tennis courts and to upset the precision of the putter on the links. Then the fact that Clover is a different tone of green to that of most lawn grasses has also been raised as an objection to its inclusion in grass seed mixtures.

But even if one were to admit all this, there are still places where the use of wild white Clover as a sward plant would prove of such inestimable value that its virtues would easily overwhelm any objectionable features which it may be alleged to possess. Indeed, as one who has a good deal of experience with lawns which burn quickly (*i.e.*, ordinary garden lawns), I am "all out" for a Clover blend, and that a strong one. As for the patchiness of such lawns, it is a matter of opinion whether a sward that shows what one may call a shadow-pattern of various shades of green, harmoniously united one with another, is not a pleasanter thing to look upon than one wholly of the same unbroken tint. A thousand times rather would I have this, or even an ancient sward consisting of two-thirds of moss, its gentle undulations soft to the tread as a pile carpet, than the crude, uncompromising grassiness of one of these artificial-looking plats which are hardly less barbaric than the bristling miniatures of the same thing one sees in seed-pans at the shows.

The verdure of wild white Clover is of a peculiarly soft and pleasing shade, and personal experience with this "weed" on poor, thin turf fully bears out the contention held by scientific investigation, *viz.*, that the presence of wild white Clover among grasses tends to encourage rather than to obstruct the welfare of the latter. This not only because the Clover is able to manufacture its own supplies of nitrogen, but because it at the same time enriches the soil for companion plants and, by covering the surface with a network of stems and succulent leafage, helps very materially to check that rapid evaporation which is the direct cause of sun-burned grass.

This native Clover, moreover, takes very kindly to the mowing machine. It springs up after the latter much more quickly than the grass wherever the soil is hot and dry, and if the mowing is done without a collecting box—always the wisest way under such conditions—it will be found that the Clover leaves very quickly shrivel and soon disappear from sight.

It is probable, though I have not tested the matter, that Clover may, as suggested, prove unsuitable for tennis lawns and golf greens; but in regard to its wearing qualities my experience is that for the average garden lawn it is every bit as serviceable as grass, and much more so where the latter is apt to burn. In some districts wild white Clover may not present such good verdure as grass during the winter months; but it is during that period that its value to the dry lawn of which we are speaking is of the least account. Even on the most sterile swards the grass will generally pick up with the autumn rain and soon make good any falling-off that may then happen to become evident in the greenness of the Clover. Though wild white Clover (the native species)

may be introduced by seed or plants into any lawn, it is seldom necessary to do this in a locality where the plant already exists. With a little encouragement it will soon appear, and with this object in view all that one need do is to dress the ground with basic slag. Enough of this sprinkled over the grass in February, until the grass is dusty, and again in June—preferably in showery weather—

will be sufficient, but an annual spring application will be found desirable. S. P.

The above article raises an interesting point and we shall be pleased to publish readers' views in our Correspondence columns. It is, of course, the difficulty of persuading Clover thoroughly to carpet a lawn which causes the patchy effect generally deplored.—Ed.]

THE NORTH BORDER

THE border on the north side of a wall or house is a source of serious consideration. Few people realise the opportunities for beautifying this or the number of plants that will not only grow but flourish on the north side. If a climber is required that will thrive, the Morello Cherry is perhaps the best that can be chosen. It is true that the fruit is not suitable for dessert, but for the purpose of the kitchen it forms a very welcome addition from the cook's point of view. This Cherry, in addition to being useful, forms a very beautiful background at certain seasons. *Jasminum nudiflorum* will flourish on a north wall and be pretty in winter and spring.

Along the border itself Ferns will lend a touch of brightness, and there are some of these which thrive on the north and which will remain green for a considerable part of the year.

Fuchsias are always popular both as indoor and outdoor plants, and it is pleasant to know that these will help to beautify the north border,

where if properly tended they will flower very well indeed. There are as well certain of the Iris family that will not only add a touch of decorative colour to the north garden, but because of their height will, if arranged in clusters, form a pretty background for plants of a more dwarfing nature.

Primroses will lend colour early in the year when in any part of the garden it is not too plentiful and so has an especial value, and the Snowdrop will bloom as well here as anywhere. Daffodils may also be safely planted to bloom early in the season, while Ivy, which may be obtained in various qualities and with distinctive markings, will also add to the beauty of the north border, if kept well within bounds.

Another flower which we must not forget is the Japanese Anemone. This may be planted in clusters, but certainly should not be omitted from this garden, while the old-fashioned but nevertheless beautiful Michaelmas Daisy should not be despised.

Foxgloves (*Digitalis*) and Pansies will, in their proper season, lend a touch of gayer decoration to this border; the former likes a shady border, while the modest but favourite Forget-me-not will grow and flower well here.

The flowers and plants mentioned do not comprise all that are suitable for planting on the north, but enough have been given to show that the garden facing in the direction from which least sun is obtainable need by no means be left barren.

Next to the choice of plants for the north garden comes the arrangement of these along the border or in the bed. Naturally, here one is rather more limited than is the case where the border faces any other direction. Perhaps an arrangement of evenly distributed clumps is the best, taking great care that all the flowers which bloom at the different seasons are so arranged that the patches of colour are evenly distributed, with the highest at the back. J. W. M.

THE SHADE-LOVING JAPANESE ANEMONE.

CORRESPONDENCE

FUCHSIA ENFANT PRODIGE.

CAN any reader tell me where I can obtain a plant of *Fuchsia Riccartoni* var. *Enfant Prodigue*? For some reason or another it does not now seem to figure in nurserymen's lists.—B.

[Our correspondent's contention that the plant is difficult to procure is borne out by a scrutiny of a great number of lists.—ED.]

LILIUM TESTACEUM.

ALTHOUGH *testaceum* has long been recognised as a good garden Lily, it cannot be said of it that it has become a general favourite, and its absence from many gardens almost leads one to suppose that it presents some cultural difficulty, or is owing to some misapprehension as to its hardiness. I am sometimes surprised to find in places where other Lilies are represented that this charming sort with its buff or nankeen yellow blooms, enhanced by red anthers, is not to be found. I find it does best when planted out in a south aspect in light, well drained soil, and is a source of pleasure when its flowers appear in July. So grown, the bulbs require no protection in winter and will go for years without needing disturbance. The colour of *testaceum* is somewhat unusual, and should induce those who are interested in Lilies to grow it.—CLAREMONT.

THE NECESSITY FOR STAKING

GLADIOLI.

WHEN putting out Gladioli in spring the mistake is sometimes made of planting the corns too near the surface instead of covering them with 4ins. or 5ins. of soil. As a consequence of this the beating of wind and rain upon the flag-like foliage is liable to uproot them. To prevent this catastrophe it is wise, where shallow planting has been done, to stake them, and I have found nothing answers better than thin bamboo canes. In inserting them it is, of course, understood that they must not be so near the corns as to injure them, and the stems should not be tied tightly.—L. W.

A ROSE WITHOUT A RIVAL!—

HIAWATHA.

IT may appear presumptuous to say of any particular Rose that it is without a rival, or even to claim for it some distinguishing characteristic over others, in these days when there are so many beautiful varieties, but beauty is fleeting and the fairest Rose of the morning has often lost much of its charm by noon! *Hiawatha* (a single sort too!) is different from any other. Of that there is no shadow of doubt, and its very remarkable trait is the longevity of its blossoms. As we know, who grow it, it yields numerous crimson clusters with golden anthers and, when the latter fall, there is revealed a white centre to the petals which rather increases their attraction than otherwise. It is these clusters so lavishly produced which often in a hot season will last three or four weeks before the petals fall, while in a normal season they will continue in beauty longer than this. As a grower of *Hiawatha* from the time of its introduction I know of no other Rose for which one can prefer a similar claim and, certainly, there is no variety that is better adapted for clothing with flowers for the longest possible time an arch or pergola. Its staying power is unique.—W. LINDERS LEA.

[Admitting that *Hiawatha* is a long-lasting variety, we think it must yield pride of place in

this particular to the fresh rose-coloured *Leuchstern*. With the latter variety (also a single Rambler, but not a *Wichuraiana* hybrid) the petals *never* fall. The blossoms eventually simply shrivel up.—ED.]

A NEAT SMALL SHRUB.

VERY easy to cultivate is that trailing alpine shrub, *Veronica Lyallii*, which rarely exceeds a foot in height. It is a native of New Zealand, being found abundantly in the mountainous districts of both the North and South Islands up to

THE NEAT VERONICA LYALLII, WITH PALE MAUVE FLOWERS.

4,500ft. elevation. I have used it as an edging to large beds of Roses and a very desirable plant it is for this purpose, quickly forming a dense thicket of growth, and if permitted to do so, it will spread into a carpet a yard in diameter. A plant of such dimensions is decidedly attractive when decked with myriads of elegant sprays of flowers. This is, too, a worthy plant for the rock garden, in which case it may be given perfect freedom and used on dry, sunny positions, where the profusion of pretty white flowers, each with a ring of pink at their base, is very attractive and lasting. The little branches root wherever they come in contact with the soil, and cuttings placed in warm frames in the autumn strike freely.—E. MARKHAM.

ROSA HUGONIS.

MAY I ask "North Wales" if he can account for the behaviour of the blooms on my bushes of *Rosa Hugonis* this year? There are plenty of them, every branch having a row of blooms on either side of it. Not one, however, has properly expanded. None has got beyond the big bud stage which gives one the expectancy of a mass of fully-out flowers on the morrow. Several to-morrows have come and then they are over without ever having been open. The bushes are very healthy and vigorous. The soil is on the stiff side decidedly, but it was well worked and enriched before any Roses were planted. They are in an oval bed which gets the morning and midday sun, but very little in the afternoon.

In the middle of the bed are three fine plants of *Rosa Moyesii*, tall and bare legged, but with a good show of leaves and buds on their upper storeys. Between the plants of *Hugonis* there are little bushes of *Willmottiae*, but this year they have hardly had a flower on any of them. Could "North Wales" tell me if what is meat for one is poison for the other? The *Willmottiae* are all outwardly the picture of health.—JOSEPH JACOB.

AQUILEGIA ECALCARATA.

"W. I." mentions in his valuable contribution on Columbines (page 316) *Aquilegia ecalcarata*, which tallies with the description of the plant by Edwin Blake Payson in the "North

American Species of *Aquilegia*," No. 19 (Easter, Vol. 226, 1891). Unfortunately, another Columbine had been previously (1889) described under the same name by Maximowicz in the "*Flora Tangutica*." This charming plant of purple colour (according to Farrer, burnt sienna brown) seems to be very rare, as I have been unable to get seed. I think that Maximowicz's plant should have the preference in nomenclature.—EAST MOLEYSEY.

GIANT MIMULUSES.

AS an old admirer of the *Mimulus* I am always looking after the developments in these attractive and showy plants, and have had reason to regret the fact that most of the large-flowered stocks are not too hardy and are liable to succumb in severe winters. A greater study of the hardiest species and varieties might well be made by those who have time and facilities for doing so, as there are many positions where these flowers could be planted with advantage. I am induced to write this note after seeing the magnificent varieties shewn at Chelsea from the Chalk Hill Nurseries, Reading. The flowers shewn were really magnificent, and if the claim made for them of hardiness and perennial character is well proved, then admirers of the *Mimulus* may well look after the Chalk Hill ones. Of different character, but very charming also, are those of Messrs. Bees, Limited, which are smaller in size. Last summer, when sojourning at Wanlockhead, some 1,300ft. above sea-level in the hills of Dumfriesshire,

I came across a fine red *Mimulus* in the garden of Mr. T. Watson, which was quite hardy there and which is doing well with me now. It is evidently one of the varieties owing their origin to *M. cupreus*, but it is quite as good and a more vigorous-growing plant. I trust the Chalk Hill ones may be as satisfactory as this. By the way, it seems essential to some of these "Monkey Musks" that they be divided and replanted occasionally. I have found this to be the case with several, including the hardy *M. Buriatti*, that good hybrid between *M. cupreus* and *M. luteus*.—ESSAY

PRIMULA WINTERI.

IT is a rare treat to see a good number of fine plants of *Primula Winteri* in a Scottish garden. It is represented by a plant or two in a fair number of places, but is not always so successful as its owners would like. The difficulty is to give it a cool spot, moist in summer, but not oversaturated with moisture in winter, and many have lost it from undue exposure to the sun and others from planting it in too dry a compost. It is frequently well satisfied with a crevice of the rockwork if planted in a vertical position. I do not think I have ever seen such a number of good healthy plants which had flowered freely in due time (winter and very early spring) than the group I saw in the garden of Mr. K. McDouall at Logan, Wigtownshire. These were growing in the joints between the blocks of peat which formed the "retaining wall" of the beds in what is called "the peat garden." The soil of the beds is mostly loam and peat but supported by blocks of pure bog-peat about the size of two bricks together. In the joints of these *Primula Winteri* had been inserted and, the peat retaining the moisture well, the *Primula* seemed to enjoy its position and other conditions. The plants were pictures of health and were splendid with their handsome leaves so finely powdered with the meal which is such a marked feature of this species. Even were it never to yield us its lovely fringed, lobed flowers of a glorious lavender-lilac it would be prized by all who can grow it successfully.—S. ARNOTT.

LILIUM PHILIPPINENSE.

NOW and again one learns of unexpected successes in certain parts of the country with plants only considered tender or half-hardy, but which, if planted in special districts in suitable soil, prove hardy and afford every satisfaction. Of such is *Lilium philippinense*. Few would expect that a Lily from the Philippine Islands would be hardy in any part of Scotland, but it has now been amply proved that it will flourish and flower in some Wigtownshire gardens, to the great satisfaction of their owners. I came across plants of it in the middle of May in the Wigtownshire gardens of Sir Herbert Maxwell of Monreith and Mr. Kenneth McDouall of Logan. They were not in flower, but were so vigorous and had flowered so well before that it is apparent that this lovely Lily is hardy there. It is a great beauty with its narrow, grassy-looking leaves and its long trumpet of snowy whiteness borne semi-erect on a slender dwarf stem. Like others of the Euhria section, it is of remarkable beauty. It is generally cultivated in pots, and those who live in all but the milder parts of the country are recommended to continue this practice, but dwellers by the sea in the warmer regions of the three kingdoms may well test *Lilium philippinense* with every prospect of high pleasure derived from the loveliness of this trumpet Lily.—NORTHERNER.

There is, of course, an alpine form of this plant hailing from Formosa (*L. philippinense formosanum*

Prie's Variety; which is much harder than the type and which certainly stands outdoors in favoured localities.—[E.N.]

FASCINATION IN IRIS.

I ENCLOSE these two photographs showing a flower of *Iris Lady Lilford* (*Pogoniris* × *Oncoeyclus*) with very complete fasciation. Each flower was complete, except in the stem; but the

THE FASCIATED FLOWER.

ANOTHER VIEW.

two flowers spread their petals in a circle as one flower, making six standards and six falls. I thought they might be of interest and perhaps worth publishing in *THE GARDEN*.—H. STEWART WACHER.

IRISES IN A NORWICH GARDEN.

THE writer thinks that if in any garden on the extreme east side of England this flower is well done, that garden is The Grove, Old Catton, Norwich. When the late Dr. Cecil Osburne was there he laid a good foundation by procuring the best obtainable, and by adding year by year and by division had an area of fully a quarter of an acre devoted to this flower. Miss McLintock is following on with the same enthusiasm.

It was my good fortune to see them in all their glory on a mid-June day. The health and vigour of the plants and the brilliance and intensity of the colours in the flowers left nothing further to

be desired. Abazar, Dominion, Lord of June and Asia struck me at once by the enormous size of their flowers. Miss McLintock said there was nothing to approach them at Chelsea Show for size. One would like to tell of the other gems of the collection, but it would only be reiterating the best kinds of the day of which mention has appeared from time to time in your columns. When I came away I wondered if the old doctor's drastic treatment of basic slag and lime, of which he wrote in *THE GARDEN* so much, was responsible for such healthy, vigorous growth.—AYTCH PEA.

NATIONAL HARDY PLANT SOCIETY.

I SHOULD like to suggest to the Executive of the above society that a reduced charge for membership might be made to *bona-fide* members of affiliated societies. I am very glad to see that this society is again to the fore.—COUNTRYMAN.

TOMATOES

The Treatment of Backward Plants.

SO far this year it has not been a difficult matter to grow fine specimens under glass where artificial heat was available early in the season. As, however, so many amateur cultivators wish to grow their main and late crops without the aid of fire-heat, they will, perhaps, meet with trouble later on, unless the weather, late in summer and early in the autumn, becomes exceptionally warm. I do not propose to deal with Tomato diseases in this note, but simply to refer to a few points that will prove helpful to beginners. The batches of plants are now all planted out, and from personal experience I know that those possessing small houses are tempted to grow too many plants in them. Where the plants are only 1ft. or so apart I would not hesitate to pull out every alternate one forthwith, that is, young, newly planted specimens. Those retained will then have a chance and prove more remunerative. Usually when overcrowding occurs the leaves are ruthlessly cut off or mutilated. Every main leaf should be retained as long as possible and kept healthy by surface mulchings with wood ashes and charred soil, or the application of nitrate of potash, not soda. Also one or two dressings of superphosphate or lime will prove beneficial not only to the plants but to the fruits, the latter colouring much better and being free from those patches of hard green skin which are so unsightly.

Those cultivators who are unable to obtain wood ashes and superphosphate of lime may use with good effect lumpy fibrous loam which has been well saturated with farmyard liquid manure and apply it as a surface mulch 2ins. thick. Fresh soil is beneficial every year, but in some instances it is impossible to obtain it. A friend living in a town used one year turfy peat from a neighbouring common. The following year he could not obtain new turf, so thoroughly soaked his old in liquid manure, placed it on the stage gins, deep and eventually gathered 12lb. of Tomatoes from each plant, the latter growing to a height of 8ft. Clear water and a small quantity of nitrate of potash were applied. I saw the crops and the photographs of them. Under glass every plant should be topped the last week in August just above the last-formed truss of flowers, then the cultivator may reasonably expect to gather a full harvest. If this is not done a great deal of really useless haulm is grown every autumn. A free circulation of air and a buoyant atmosphere are two essentials in the successful cultivation of Tomatoes late in the season. G. G.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Dwarf Beans.—A small sowing of these may be made, but it should be understood that they may be destroyed by frosts just at the time when they begin to be productive. Nevertheless, as a chance crop, it is worth the risk.

Broad Beans.—The tops are often infested with black fly, so it is advisable to remove them when several trusses of flowers are seen, because this aphid only feeds on the young leaves. A dusting of tobacco powder or a weak solution of insecticide will destroy the pest.

Broccoli.—Continue to plant out Broccoli and Winter Greens until the requisite number are planted and, if the weather proves dry, a liberal watering will be necessary. Use the hoe freely among the earlier crops and fill up any gaps in the rows.

Vegetable Marrows.—These are growing freely and when the roots need it a thorough soaking of water should be given, and weak liquid manure afforded at intervals of a week will prove beneficial. If this is not available, a light sprinkling of artificial manure may be given, especially during showery weather. Weak and worthless shoots should be removed and other growths pinched occasionally to encourage the early formation of the fruits.

Carrots.—During the present month a sowing of a stump-rooted variety may be made with the object of securing young roots for the kitchen in the autumn. When the seedlings are sufficiently advanced thin them slightly and keep the ground free from weeds.

Onions.—In many gardens this is an important crop, and it behoves the grower to give every encouragement to the plants by frequently hoeing the soil and affording an occasional sprinkling of old soot between the lines. Weak liquid manure will help them, and a suitable substitute will be found in a reliable artificial manure if used in moderation during showery weather, or it may be watered in.

The Flower Garden.

Flower-Beds.—Plants that were put out in May are now well established, although growth is not so far advanced as last year, while annuals sown in the open have failed in several cases. The beds will need the hoe occasionally, while all weeds and decayed foliage should be removed. Such plants as Ivy-leaved Pelargoniums, Phlox Drummondii and Verbenas may need pegging down to the soil. The grass between the beds should be mown frequently, the edges clipped and all gravel walks kept free from weeds so that the whole presents a clear and smart appearance.

Campanulas.—The perennial varieties are almost indispensable for the borders and rock garden, and as they are readily raised from seeds, now is a good time to sow in pans of light soil. Give a thorough watering before sowing, and after this operation has been completed place the pans in a cold frame and see that the soil never becomes dry. Until germination is effected the lights may be covered with a piece of canvas or mats. This will maintain a uniform moisture, and the seedlings will appear more regularly. When the young plants are large enough to handle, prick them off in boxes or cold frames containing a few inches of light open soil, and here they may remain until next spring, when they should be transferred to their flowering quarters.

Mimulus.—These are favourites of mine, and last July I scattered some seeds on the ground, where they germinated freely. They stood the winter, and quite early this spring they began to flower, while a few weeks later the display was very fine. The Giant forms are most effective and produce enormous flowers of various shades and markings.

Tulips.—The May-flowering section which were lifted from the beds in May should now be taken from their temporary quarters and stored in a dry shed until the autumn. Clean the bulbs of all loose material, and the small bulbs may be picked out with a view to planting them in the reserve garden, where they will attain flowering size.

The Hardy Fruit Garden.

Apples and Pears.—So far as I can see, the crop is a poor one in this neighbourhood, but a few isolated trees are bearing a number of fruits. Where the crops are heavy, thinning of the fruits should be resorted to, for it is a great mistake to overcrop, especially young trees. First remove all deformed specimens and those not fully exposed

to the sun, but see that the crop is distributed equally over the tree. If fruit is required for exhibition, the thinning should be more severe and suitable varieties selected for the purpose.

Cherries.—Early varieties will be ripening their fruits, and as soon as these are gathered the trees should be given a thorough cleansing with a solution of some reliable insecticide. Examine the growths and see that the far twigs have not been tied too tight, or the bark will be cut and the shoot injured. Continue to tie in the growths of Morello Cherries.

Fruit Under Glass.

Vines.—The rods from which the bunches have been cut should not be neglected, and it is recommended that the foliage be syringed twice each day whenever the weather is hot. The borders, especially those inside the house, should be kept moist, and when the necessity arises for applying water it should be done thoroughly so that the lowest roots receive their share. Open the ventilators to their fullest extent and allow the lateral growth to develop, but overcrowding should be prevented. When the growths have ripened and the foliage falls, no more water or syringing will be needed until the rods are cleaned and started next season. Later Vines will be ripening their fruit, and here a little ventilation should be allowed throughout the night. All split and decayed berries should be removed immediately they are seen, or the bunch will soon be ruined.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Jerusalem Artichokes.—Run the Dutch hoe through the lines and, a few days later, earth up the plants with the draw hoe and, if the soil is not fairly loose, slacken it with a fork prior to earthing up.

Globe Artichokes.—Endeavour to have the "heads" used as soon as they are fit, as they lose their tenderness and succulence before they quite attain full size. Any that cannot be utilised should be cut as soon as they get out of season, for if left to develop they make a heavy drain on the plants.

Spring Cabbage.—It seems like looking a long time ahead, but in the North, if one expects to cut Cabbage in April, the seed should be sown by the middle of July. There is a considerable variety to choose from, but the following can be thoroughly recommended and pretty much in the order in which they are here given: Harbinger, Sutton's April, Ellam's Early and McEwan's Vanack.

Vegetables Under Glass.

Tomatoes.—One sometimes sees plants that are ripening off their fruits almost entirely denuded of their foliage. This is bad policy, as plants so maltreated produce tough-skinned fruits with a lack of succulence. No bad results will, however, follow the removal of an occasional leaf or portion of a leaf where such overlap and may, consequently, encourage the spread of fungoid disease. Later crops should be attended to in the way of removing laterals, top-dressing and giving occasional doses of weak liquid manure.

Cucumbers.—Plants under glass that are becoming exhausted should be cleared away and a second crop planted in their stead. If plants have not been prepared in anticipation of this, cuttings can be readily rooted if kept close and shaded. Those who have plants in frames can generally get rooted shoots quite readily, or if necessary they can be quickly rooted by layering. If the supply of Cucumbers is in excess of the demand for current use, the fruits should be cut when still quite small, and will be useful for pickling purposes.

The Hardy Fruit Garden.

Training Young Trees.—Give attention to the training of young trees, whether on walls or trellis, the building up of a healthy well balanced specimen being more important than the securing of a certain amount of fruit at the present stage. Any badly placed intractable shoots should be removed.

The Pleasure Grounds.

Flowering Shrubs.—Remove in due course the spent flowers of such plants as Rhododendrons, Lilacs and Spiræa arifolia and Anthony Waterers. The same attention should also be given to such herbaceous plants as the following, whether in

the shrubbery, the wild garden or on the edge of lawns: Spiræa Arneus, Senecio cordifolia and tanguticus and Cranberry cordifolia. Should a spell of drought occur, the following moisture-loving plants should not be allowed to suffer for lack of water: Gunneras, Rodgersias and Saxifraga peltata.

Lawns.—Mow all lawns weekly, while tennis lawns, bowling greens and such-like should be mown twice a week. These playing lawns must also be frequently rolled, preferably when they are in a moderately moist condition. Clip edges fortnightly, and keep walks and drives free from weeds.

The Flower Garden.

Flag Irises.—As these pass out of bloom cut away the spent flowers. Break up and transplant any scarce variety that it is desired to increase. Do not bury the fleshy rhizomes, as the floriferousness of these plants largely depends upon the thorough ripening of these rootstocks.

Dahlias are very subject to attacks by earwigs. The common custom of trapping them by means of an inverted flower-pot placed with a little moss in it on the top of the stake, while quite efficacious, is rather inartistic. Pieces of crumpled brown paper or sections of beanstalks placed in an obscure position among the foliage are quite as efficacious and do not offend the eye. Tie and thin the shoots as growth proceeds.

East Lothian Stocks.—These attractive flowers are often sown too early in the season; if sown now, they will have every chance of passing safely through the winter except in the colder districts and on badly drained soils, in which cases summer sowing need hardly be attempted.

Biennials.—As the earlier crops in the kitchen garden are used up, the vacant ground should be forked over and utilised for the reception of Wallflowers and such-like plants. Put the plants in nursery lines about 9 ins. apart, allowing 6 ins. between the plants in the line. By this means the plants will become bushy and strong by the time they are to be transferred to their flowering quarters in the autumn. It is good policy to plant some portion of the stock of Wallflowers a little wider apart, to be left in position all winter to furnish cut flower in the spring so that those in the flower garden may be left intact. Sweet Rockets should be transplanted direct from the seed-bed to their flowering quarters.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian.)

GREENHOUSE AND CONSERVATORY.

Azaleas of the indica section, as they complete their growth, should be stood outdoors in an open position. Large plants should be partly plunged to prevent them blowing over. Other hard-wooded plants as they complete their growth should also be stood outdoors, all large plants being securely staked and secured against stormy weather. They include most of the hard-wooded Australian, South African and New Zealand plants, and most of them benefit by having their flowering wood hardened and ripened before winter.

Humea elegans.—This is very useful for the conservatory, and seed should be sown some time during this month and again next month, according to the requirements of the establishment. Humea elegans is generally regarded as being somewhat difficult to grow successfully, and this is undoubtedly true as regards the final stages of growth, but in its earlier stages there is no difficulty, especially if it is grown perfectly cool and watering is carefully done at all times.

Stocks.—If these plants are required in flower early in the year, seed should now be sown. Stand the pots in a cold frame until the seeds germinate. The seed should be sown very thinly, as the young plants are very apt to damp off if at all crowded. When large enough to handle the seedlings should be potted off singly into small pots, using for the potting compost a good loam with or without the addition of a little leaf-soil. Instead of sand some old lime rubble should be used, as lime in some form is very essential for the successful cultivation of Stocks. Good plants can be flowered in 5 in. or 6 in. pots and grown throughout in cold frames, except during the winter, when it is an advantage if they are placed in a cool, airy pit or greenhouse. The intermediate Stocks are best for pot work, also a good selection of the Beauty of Nice varieties. Seed should be procured from a good source, as good strains are very important.

Canterbury Bells are very useful for the decoration of the conservatory. Seed should be sown thinly in boxes and germinated in cold frames, afterwards transferring the young plants to the reserve garden in a piece of well manured ground. From there they should be lifted during autumn and placed in suitable-sized pots according to the size of the plants. Well grown plants will require six, or ten, pots, but if space is a consideration during winter they may be placed in smaller pots, giving them a shift into larger ones during the spring.

Double Wallflowers of the so-called German varieties are very useful for pot work, and seed should now be sown and the young plants grown on in the same way as Canterbury Bells.

Campanula persicifolia and its varieties are all excellent for growing in pots, and entail very little trouble. They should be lined out in the nursery garden during spring, or even at this time, where they should make good strong clumps for potting up during autumn. During the winter they may be stood at the bottom of a wall, protecting the pots with ashes or such-like material to safeguard the pot from frost. The fine variety *Telham Beauty* makes a splendid pot plant and flowers over a long period. This is really *Campanula persicifolia* var. *maxima*, which is quite an old garden plant. If this plant is grouped with *Nicotiana suaveolens* in the conservatory, it makes a very charming picture. For this purpose the *Nicotiana* should be sown early in the New Year.

Nicotiana suaveolens.—If seed of this dainty white-flowered Tobacco plant is sown at this time, the subsequent plants will flower during the autumn. Seed of this plant is listed by Messrs. Sutton and Sons as *Miniature White*.

Nicotiana Sanderae is an excellent plant for the conservatory. If seed is sown at this time, very bright and useful plants will be had for the autumn months. They should be grown in cold frames in their younger stages, removing them to a cool, airy greenhouse as they require more head room.

Pelargoniums of the Show and Regal types are not now so commonly grown as they used to be; still, they are very useful for the conservatory. As they pass out of flower they should be stood in cold frames or at the bottom of a wall in a sunny position, where they may remain until they are cut back during August. At that period the plants required for growing on should be given the shelter of a cold frame, any shoots removed being used as cuttings for increasing the stock. J. COULTIS.

Royal Botanic Gardens, Kew.

GENERAL BULBGROWERS' SOCIETY OF HAARLEM (HOLLAND).

THE various Floral Committees of the above Society have made the following awards:

FIRST CLASS CERTIFICATES.—Breeder Tulip Red Monarch (Breeder Tulip Panorama & Feu Ardent), deep scarlet with orange glow, centre yellow. Cottage Tulip Mongolia, dark creamy yellow (seedling); Dutch Iris ten Cate, self-coloured dark yellow; Iris filifolia (*Niphium præcox*) The First, light blue standards, falls very soft blue, very early.

AWARDS OF MERIT.—Double Early Tulip l'Aurore, soft carmine; Darwin Tulip Turner, pink, white bordered; Cottage Tulip Jeanne Désor, golden yellow with orange-red stripes; Aster alpinus Dunkle Schöne, bright violet large-flowered double; Aster subcæruleus Venus, light violet, centre orange, large flowered and long stemmed; Armeria cephalotes Miss Max, a very soft violet rose (seedlings); Iris filifolia (*Niphium præcox*) D. Haring, standards very soft grey blue, falls creamy white with yellow blotch (seedlings); Iris nitolia (*Niphium præcox*) P. de Moulm, standards dark indigo blue, very long, falls blue with clear yellow blotch (seedlings); Dutch Iris Hoogstraten, self-coloured light blue, yellow blotch; Dutch Iris van Sevel, standards grey blue, falls white with big yellow blotch; Iris pallida Riese von Cönnern, bright sky blue, very big flowers on long stems; Iris squalens Ambassadeur, standard bronze, violet shaded,

falls purple-violet; Isotolion Ledebouri, dark blue, early; Lilium unbellatum splendens, vermilion with orange (seedlings); Pæonia Whitmaniana rosea, soft pink (seedlings); Pyrethrum hybrid. Eileen May Robinson, soft pink, large-flowered single.

New Gardens for Ramsgate.—In the presence of nearly 2,000 spectators Dame Janet Stancomb-Wills, D.B.E., on Friday, June 15, handed over to the town of Ramsgate the Winterstoke Gardens, the "beauty spot" created at her own expense on the East Cliff. The Mayor of Ramsgate, Sir John Burnet, A.R.A., R.S.A. of London (who designed the gardens), and the members of the Town Council were present. Sir John Burnet, on being asked to give a description of the work carried out in forming the gardens, said that they formed the first portion of a comprehensive scheme prepared by him for the improvement of the Ramsgate front. The main feature of the new garden was a semicircular-shaped colonnade placed in a recess some 20ft. deep, cut out of the chalk cliff. Access to this recess was given by a pathway sliced off the face of the cliff leading down from the level in each direction to the centre. The face of the chalk cliff along the side of these approach paths and in the recess itself has been "rockified," the rock clothed with such shrubs and plants as will stand the severe conditions prevailing at Ramsgate. The secluded position of this colonnade would enable those sitting there to enjoy the sea air and at the same time be protected from the sun and east wind. On the upper terrace, approached from the lowest level by two broad flights of steps, are the gardens proper, in the centre of which, and immediately over the shelter, is a circular pool enclosed on the north side by a semicircular Roman seat, from which there is a magnificent view of the sea. This seat is backed by a hedge of golden Euonymus. At one end of the site is a formal seat and pool, in colour to match Portland stone, and at the other a more informal pool backed with rock. At the north end is a "rest garden" sheltered from the north winds, the breadth of turf and surrounding planting giving it a most restful appearance. On this higher level are ample lawns, paths and seats. A charming feature is a series of geometric flowerbeds cut out of the turf, each bed being massed with low-growing plants. The colonnade, Roman seat, pools and other formal features are formed of reinforced artificial stone. Messrs. Pulham and Son of 71, Newman Street, London, W., have carried out the whole of the work, including the laying of the lawns and planting of trees and shrubs, which are all selected to suit the soil and climate and to stand the rigorous conditions prevailing at Ramsgate. The bulk of the shrubs and trees had to be planted while small, and as many of them are by nature slow growing, it will necessarily be some time before the full effect of this generous gift of Dame Janet is realised. Dame Janet Stancomb-Wills, in handing the gardens over to the Mayor, on behalf of the town of Ramsgate, said that the laying out of the ground had given her the greatest possible pleasure for two special reasons. The first was the joy of turning what was once a wilderness into a thing of beauty, the second being that in carrying out the work a large amount of previously unemployed local labour was found employment for the twenty-one months the work had been in hand.

Aldenharn House Gardens.—The Hon. Vicar of Gibbs has again kindly consented to the opening to the public of the gardens of Aldenharn House on the Saturdays of July, August and September, and the August Bank Holiday Monday, on the

same conditions as in previous years, viz., that children must be accompanied by a grown-up person and that dogs will not be permitted. These facilities will not be available on Saturday, July 7, as this is the date of the annual floral fête of the Elstree and District Horticultural Society at Aldenharn Park, when admission is only possible on payment of the Society's entrance fees.

A Large Shipment.—Messrs. Sutton and Sons of Reading have recently despatched a large consignment of agricultural seeds to their New Zealand agents, Messrs. J. G. Ward and Co., Limited. These seeds, together with the packages, which included twenty-five galvanised iron tanks, had an aggregate weight of 36 tons, and eleven railway wagons were required to convey them to the docks.

An Alpine Violet.—Not many growers of rock plants cultivate the attractive little *Viola bosniaca*, but it is worth remembering by those who have a penchant for the Violet species. It is small in size, it is true, but that is no disqualification for a rock plant, and its colour is a good warm pink. It is often put down in works of reference as flowering in July and August, but it anticipates that time by a long way and is in blossom in May. It seems to be a good perennial and may be increased by seeds or cuttings.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

SHRUBBY ROSES FOR THE CUMBERLAND COAST (M. H. S.-N.).—As the common *Rosa rugosa* does so well with our correspondent, a number at least of the bushes planted should be *Rugosa* Hybrids, which flower from June to September. Some of the best are *Blanche Double de Coubert*, semi-double, white; *Mme. C. F. Worth*, double, reddish carmine; *Mme. Georges Bruant*, semi-double, white; *Mrs. Anthony Waterer*, crimson, semi-double; *Conrad F. Meyer*, silvery rose; *Nova Zembla*, white; *Flambriata*, bluish. These are all pleasingly fragrant. The Scotch *Roses*, *Rosa spinosissima* varieties, should thrive in such positions, also *Rosa Hugonis* and *R. Willmottiae*, but these only flower in June and early July. *Fellenburg*, rosy red; *Grüss an Tepitz*, crimson; *Rosa alba*, white blossoms and attractive fruits in autumn, should also suit the position. Many of the newer single and semi-double Hybrid Tea *Roses* are perpetual flowering, but they are unsuitable for semi-wild planting.

CARNATIONS AND DELPHINIUMS ATTACKED ("Bell," Belfast).—The pest present is the springtail in large numbers. It is generally most abundant in soils containing very large quantities of vegetable matter. Reduction of this and good drainage are aids to its extermination and hot water the best way of killing it.

ROSE OF SHARON (J. B., Reading).—Rose of Sharon is the English name for a handsome and exceedingly hardy member of the St. John's Wort family with golden yellow, saucer-shaped blossoms 2ins. to 3ins. across. It will grow and flourish under the shade of trees and is practically evergreen. It reaches a height of a foot or so, and its botanical name is *Hypericum calycinum*. It would certainly not revive after being dried for a year or more, but perhaps this peculiarity was legendary. The plant is obtainable from any nurseryman and is very moderate in price.

KITCHEN GARDEN.

ONIONS ATTACKED (E. B.).—The Onions are attacked by the disease known as white rot, due to the fungus *Sclerotium ceporum*. There is no cure for plants once attacked, and they should be destroyed so as to avoid, so far as possible, infection of another crop. The ground should be limed this autumn.

MISCELLANEOUS.

TESTING SEEDS (G. W. G.).—It is not possible to tell by microscopic examination and with absolute certainty whether a seed is alive or not. An electrical method was reported at one time, and it might be well to consult such works as those of Pfeffer, Jost, Bosc and other physiological writers, where references to special papers will be found. A useful list is given in Vilmorin's book on the vegetable garden.

NAME OF FRUIT.—Miss H.—Apple Grange's Pearmain.

Special Offer of the following Collections:

THREE GUINEA COLLECTION.

2 AMBASSADEUR (Vilmorin). A late strong plant with stout stiff stems about 4ft. high. Flowers very large with smoky reddish-violet standards, the falls being a velvety dark reddish-violet of great substance and almost horizontal. Beards and styles yellow. A magnificent variety. A.M., R.H.S., 1921.

2 ASIA (Yeld), A.M., R.H.S. This distinct and beautiful variety is unquestionably one of the most glorious Irises in cultivation. It is an exceedingly strong and tall grower, very free flowering with individual blooms of the largest size. The standards are pale lavender suffused and reticulated yellow at the base, falls light violet-purple, paler at the edges, and heavily

reticulated at the haft, with a bright yellow beard. Height 4ft. to 4½ft.

2 BLACK PRINCE (Douglass), A.M., R.H.S. An exceptionally fine variety, S. velvety blue-purple, F. rich deep black-purple. Free flowering and late. Height 2½ft.

1 ED. MICHEL (Vilmorin), A.M., R.H.S. A grand Iris of imposing appearance, tall spikes with large flowers finely held and of splendid shape, the standards broad and frilled, the falls of great width; the colour is a distinct deep reddish petunia-violet, the falls slightly deeper than the standards. One of the finest varieties in cultivation.

2 HALO (Yeld). An exceedingly fine Iris with flowers of the largest size and

good quality. S. light violet, F. bluish violet. A good strong grower. Height 3ft.

2 LORD OF JUNE (Yeld). A very strong grower with massive flowers of great size. S. palest lavender blue, F. rich deep aniline blue. A.M., R.H.S. This is one of the finest Irises in cultivation.

1 MAGNIFICA (Vilmorin). A fine strong plant with branching stems reaching a little over 3ft. high. The flowers are extraordinarily large, 6ins. high, and sweetly scented. Standards light violet-blue, falls dark reddish violet, with brown stripes at the base and yellow beards. One of the most strikingly beautiful new varieties.

TWO GUINEA COLLECTION.

3 ALCAZAR (Vilmorin), F.C.C., R.H.S. One of the handsomest bearded Irises in cultivation, strong constitution, stout much-branched stems bearing many gigantic flowers. S. bright deep aniline blue, F. rich deep velvety violet-purple, heavily reticulated at the haft, with a prominent yellow beard. Very tall.

2 ARCHEVEQUE (Vilmorin). A brilliant coloured variety of French origin. S. rich violet-purple, F. bright velvet crimson. An exceedingly fine flower. Rather dwarf.

2 CREPUSCULE (Vilmorin). A fine violet-blue self with very large

flowers; extra good, one of the most beautiful and decorative blue varieties in cultivation. Very free flowering and reliable. Not very tall, but a good grower.

3 ELDORADO (Vilmorin), A.M., R.H.S. One of the most distinct and rich colour combinations. S. yellowish-bronze shaded beautifully with heliotrope; F. bright petunia-violet touched down the sides with the bronze-yellow of the haft, with a prominent rich yellow beard.

3 PALLIDA DALMATICA (Princess Beatrice). The finest of the Pallidas, has a tall stem of very large pale blue flowers, broad glaucous foliage.

3 PROSPER LAUGIER (Verdier). A great improvement on the well known I. Jacquiana, flowers are much larger and brighter in colour. S. snuff brown slightly suffused heliotrope, F. deep plum violet, veined deeper, heavily reticulated base, with prominent yellow beard. One of the best varieties, very handsome, and grand in the mass.

1 PROSPERO (Yeld), A.M., R.H.S. A fine strong-growing variety with flowers of the largest size. S. pale lavender, F. rich deep violet purple slightly paler at the margins, heavily reticulated at the haft. This is one of Mr. Yeld's best varieties.

ONE GUINEA COLLECTION.

1 AMBIGU (Vilmorin). A very fine variety, a strong grower and free flowering. The standards are a clear smoky red and the falls a velvety reddish brown. Height 2½ft.

2 DEJAZET (Vilmorin). A magnificent variety of distinct and most beautiful colouring. The standards are a dusky rose-orange, and the falls a clear reddish-violet, a striking and attractive combination of colours. A robust grower of medium height

2 EMPRESS OF INDIA. A grand new variety, with very large flowers of a lovely soft pale blue, well arranged on the stem. Free flowering.

2 LORD OF JUNE (Yeld). A very strong grower with massive flowers of great size. S. palest lavender blue, F. rich deep aniline blue. A.M., R.H.S. This is one of the finest Irises in cultivation.

1 OPERA (Vilmorin). A magnificent variety, a fine vigorous grower and

free flowering, with blooms of medium size. The standards are bright rich pansy violet shading to brownish violet at the base, and the falls a rich velvety violet purple. A very striking Iris. Height 2½ft.

1 RAFFET (Vilmorin). A late variety growing 2ft. to 2½ft. high, with very large flowers. The standards and falls are a glorious uniform dark blue, the falls being striped at the base with white. Beards yellow and styles bluish.

SEND FOR PLANS OF IRIS GARDENS.

BARR'S TALL FLAG IRISES

Awarded the R.H.S. GOLD MEDAL at the GREAT IRIS CONFERENCE SHOW, June 7th and 8th, 1922.

The Iris is the "Orchid" of the flower garden, its blossoms being the most rich and varied in colour of all hardy plants. It should be extensively planted in flower and shrubbery borders and wild gardens. When established, the plants yield a great quantity of bloom.

Nurseries - - BATH ROAD, TAPLOW, BUCKS.

The Orpington Irises

OUR collection of these magnificent hardy garden plants is now world famous, and is probably one of the finest in existence at the present day. Our ground is particularly suitable for their cultivation, and our stock of some 70,000 plants includes practically every variety of merit.

We are the sole distributors of the New Varieties raised by Mr. W. R. Dykes, and we also distribute many of the wonderful seedlings raised by Mr. A. J. Bliss, while all the best of the recent Novelties raised in America and on the Continent may be seen at our Nurseries.

We believe our plants to be the best obtainable, and this opinion is endorsed by our customers, as shewn by the following extracts from recent letters:—

- (1) "The two orders have been duly received and in most excellent condition. I must acknowledge the fact that you send out very fine stocks, much more vigorous than I have received from other growers."
- (2) "Your exceptionally fine Iris roots to hand yesterday."
- (3) "The Rhizomes were all fine; they are the best and largest I have received."
- (4) "The Iris roots arrived in excellent condition—the best roots I have ever received from any grower; in fact, I must say that they have an entirely different appearance from all others received: big robust roots with plenty of vitality in them."

Why not have THE BEST in your garden? Our Iris Catalogue, which is sent free on request, will give you full information about them.

A Perfect Spray

The most economical and efficient type of hand sprayer for all plants and flowers is the Abol. It gives a strong spray, which may be varied from fine to medium or coarse, as desired.

Abol Patent Syringes embody the finest materials and workmanship. Many of them have been in use for over 20 years.

Full particulars, together with an interesting book on Garden Pests, will be sent to anyone, gratis and post free.

Abol Patent Syringes are specially recommended by the National Rose Society.

Abol

Patent Syringes

No. 4 (1 1/2 x 1 1/2) - 16/4

Notes from Maidstone.

STRAWBERRIES.

The increased rainfall of the past twelve months has greatly benefited these plants. Our beds this year have never looked better, and the crop of fruit, given some sun, will be phenomenal. We shall hope, therefore, to be able to supply vigorous runners in the autumn, and are now booking orders for early delivery.

[JULY 14, 1923.]

THE USE and ARRANGEMENT of BEARDED IRISES

THE choice of position in the garden for Bearded Irises is a matter that depends to a very great extent on the garden. It would be absurd to attempt to devote a portion of a small or even a moderate-sized garden to Irises exclusively. It is also unnecessary. Where space permits it is a very excellent arrangement for many reasons, but it must be remembered that, wonderful as is the range of colour and diversity of form, the flowering period is restricted to certain months in the year, and that when out of flower they are no more attractive than many other plants that are just as indispensable.

In gardens where space is limited there are two positions in which they can be used successfully. One is in the vacant spaces that always occur in the front of shrubbery plantings. Bold masses planted in such positions are always attractive during the flowering period, and even when there are no flowers the sword-like green or grey foliage adds a useful note to the shrubbery. Used in association with flowering shrubs they are wonderfully effective. Think, for instance, of the effect of *Viburnum tomentosum*, a snowy mound of white flowers associated with groups of the taller Bearded Irises. But whether the shrubs are evergreen or deciduous flowering, the introduction of Irises among them will always produce some wonderful effects.

The colours of the Irises have to be rightly chosen, and either contrast or harmony can be achieved. There are, for instance, some evergreen shrubs with cool grey foliage at Iris-time. With these as a background it is impossible to go wrong. The violet and blue shades of the Irises will melt softly into the tone of the shrubs, or the warmer-coloured forms light up to more vivid splendour

by virtue of the contrast with the coldness of the shrubs' tones. Wistarias grown as bush specimens also associate well with Irises.

Some gardens are too small to have room even for a shrubbery that offers much opportunity for this sort of treatment, but few are so small that they cannot afford space for them in the herbaceous border. Nor is there anywhere in the garden more suitable for them, and startlingly beautiful effects can be obtained by associating them with other perennial plants in this way. A May or June border in which are planted groups of Irises in positions in which they borrow from some plants or lend to others some charm of combination is by far the happiest result that can be achieved throughout the garden year. Years ago it was discovered that one of the best plant combinations was Lupins and Irises. Since then both plants have progressed enormously in the colour range offered to the gardener. For some time it has been truthfully asserted that there is no other genus that has the colour wealth of the modern Bearded Iris, and now hybridists offer us Lupins of innumerable intermediate shades ranging from

pure white to black purple and maroon, through every shade of pink, blue, violet, cream, buff, orange and even crimson. Here, then, is a wealth of colour large enough to meet the most exhaustive demands that may be made on it, and the garden-lover who cannot have his or her heart's desire in colour combination with them, lacks the knowledge to choose the right material.

It is all very well for some very good gardeners, both amateur and professional, to scoff as they do at what they call "colour fads in the garden." True, sometimes this colour arrangement is carried to extremes, and where harmony is aimed at monotony is often achieved. I have heard it argued that Nature never groups her colours. Nor does she. Nature makes no attempt to harmonise the music of the woodland, such as the warbling of birds and the sound of falling water. But in music the sounds are arranged, and in good painting the crude colour is rejected and softened to fine harmony. All sound and all colour is of Nature, and it is only its selection and arrangement that makes art. The very essence of good gardening is that it selects, civilises and arranges, and the

garden is just as much the domain for artistic endeavour as is the music room or studio.

So in planting the Bearded Irises, if by care in colour association the true value of the plants can be emphasised, the delicacy of tone of some brought out, the vivid richness of others strengthened, this is assuredly desirable.

In the herbaceous border every group of Irises should form a selected picture. The potential variety of colour grouping is so great that it is impossible to particularise in the present article, and in any case the selections for colour grouping must be left to individual desire. A group of dark purple Lupins will suggest to some a splash of the

EARLY JUNE—A FEAST OF BEARDED IRISES.

BEARDED IRISES BY THE PATHSIDE,

IN SEMI-NATURAL GROUPING

AND LINING A PERGOLA.

brightest golden yellow Irises, to others a grouping of the amber, bronze and copper tones. A group of pale yellow *Lupinus* will likewise produce in some a desire for the combination of rose shades of Irises, in others the richest of violets. The lightest, bluest violets of the Irises are not good when planted in association with the bluest of the *Lupinus*.

Some other excellent plants for association with June flowering Irises are the *Ligerones*—*Quakeress*, *B. Ladham's*, *Asa Grey* and others. *Nepeta Mussini* (*Catmint*) is another plant that is very useful for this purpose. Some of the *Aquilegias* also planted in masses around groups of Irises are capable of producing some enchanting results and *Pyrethrums* in bold masses grouped near Irises, the colours of both being carefully chosen, will give rich results. Grey foliage, especially the young tender grey green of *Artemisias* and *Achilleas*, with pale violet or mauve-tinted Irises give wonderfully soft and pleasing effects. One of the most striking effects I have seen lately was a large mass of *Cheiranthus Allioni* from which rose the rich purple of a late May or early June flowering Iris. Royal purple and gold this!

These are a few of the plants that can be associated with the Iris in the herbaceous border, but next them should always be grouped plants that flower at an earlier or later period, so that the continuity of the colour effect throughout the border is maintained.

In the larger garden, wherever it is possible, the finest results of all are obtained by devoting a portion to the cultivation of Irises primarily, just as one does for *Roses*. Gently undulating land, grassy paths winding between banks of the glowing tufts and exquisite forms of the modern Irises, offer a realm of endeavour well worthy of the most enthusiastic exploration. Informality in arrangement is preferable and colour grouping desirable, and this is easy now that most catalogues divide the Irises up into colour groups and state height and time of flowering.

One word of warning. There is a tendency to plant all sorts of things in grass. "Naturalising" it is called, and some very charming effects are obtained in this way when the right material is used. Do not, however, do it with the Bearded Irises. It is not naturalising them but murdering them. They will not stand it, and if they are to succeed the grass must be kept clear of their roots. So long as the grass of the path is kept even a few inches away they are happy. Another warning is, do not plant them in dense shade and expect them to do more than grow foliage luxuriantly for a time. To flower they must have sunshine, and the more they get the better they like it.

The use of Irises to border a pathside or to line a pergola seems to be extending. For this purpose varieties should be selected with good foliage, so that the best possible effect may be produced when the plants are out of flower—some fifteen-sixteenths of the year if a mass of colour is sought for at one time and seven-eighths of the year, anyhow! The pergola idea—so that the pergola be not too shady—is an especially good one because it is easy to arrange a sufficiency of colour on the pillars for the greater part of the summer and autumn, while an edging of *Nepeta* might, of course, be arranged to the Irises, but this excellent plant is in many gardens being overdone. It is truly an admirable foil for many brilliantly coloured flowers, particularly *Roses*, but one can have too much of a good thing, and one certainly does tire of *Nepeta* everywhere. *Madonna Lilies* and *Delphiniums* alongside a pergola are effective, but I notice there is no copyright in the idea. Perhaps Bearded Irises would make a pleasant change!

TRAVELLER.

A SELECTION OF THE BEST JUNE-FLOWERING IRISES

OF late years the tall Bearded Iris has become a very aristocratic representative of the flower garden. He has moved, as it were, from the region of Bloomsbury and its purlieus to the more dignified environment of Mayfair, as befits his more exalted circumstances. In the Bloomsbury days the speculative builder could afford to mass Iris roots among the other riff-raff of the local plant seller in the oblong space surrounding his very speculative building; to-day, the real florist enthusiast hesitates about the cost of starting a collection of the newer good Irises. That is the result of having one's being in Mayfair!

But all good things cost money, and the value, interest and pleasure obtained from a dozen well selected varieties of modern Irises, even if they cost a couple of guineas or more, make this outlay a highly satisfying investment. All the varieties valuable from a garden point of view are not necessarily expensive, but it is only natural that many of the very finest are highly priced. Were it not so one could accept the theory that the flower was not being improved as it ought to be.

In America there is a very energetic body of flower-lovers called the American Iris Society, and among their many beneficent activities they have evolved an Iris symposium. This symposium has nothing to do with rounds of bacchanalia, but rather the bringing together of a host of votes on the relative merits of every known variety of Iris. These votes were recorded on a scale of 10, but bearing in mind that progress towards perfection was still going on, the apex value of 10 was not allowed to be used for present-day varieties, and in actual fact only one variety reaches the elevation of 9.6. It stands to reason that, where a number of Iris experts have deliberately weighed up and recorded their opinion of every Iris known to them and the average value of all votes brought down to a decimal point by the recording committee, the results can be taken as a fairly dependable guide for the Iris purchaser who is not an expert. In briefly describing a few of the finer Irises of to-day I have given the symposium value in parentheses after each name, thus—*Crusader* (8.7), and if the list is to be of any economic value to the reader I have thought it only fair to quote the generally ruling price of the varieties also.

Standing at the top of the symposium list is *LENT A. WILLIAMSON* with a rating of 9.6 and a market value of 25s. to 30s. per plant—an expensive luxury. While I should probably not place this new variety quite at the top of the poll, there is no gainsaying its position as a flower of striking merit, of which the glory lies perhaps more in the refinement and majesty of its build than in its colouring, though that is dignified and pleasing. The smooth, broad falls are velvety pansy violet and the standards lavender.

PALLIDA PALMATICA var. *PRINCESS BLAIRICE* (9.5), 2s., comes next on the list, and is generally considered as fine as any of the so-called light blue Irises. It is a cool silvery lavender self of robust habit with broad, glaucous leaves, its only fault being that if poorly or carelessly grown the colour is not constant, becoming stringy or streaked. A very fine Iris! *Ambassadeur*, *Ballerine* and

light violet-blue, well rounded and elegantly waved at the margins; falls similar in tone, but slightly deeper in the shading. The sweet scent of this variety is an additional charm to a very desirable plant, and it can be procured for 7s. 6d.

DOMINION is surely the most talked-of Iris in existence. In spite of the massive size of its leaves it is somewhat slow-growing, which, coupled of course with its fair reputation and high quality, accounts for its artificial price of three or four guineas. Magnificent as *Dominion* doubtless is, those who have seen some of Mr. Bliss's newer seedlings of similar type recognise that its rating is too high to stand for the future. While the same argument may apply to all Irises in a sense, it is more acutely applicable to *Dominion* because of its being the forerunner of a new and distinct race of seedlings, some of which will, doubtless, eclipse the parent in quality. The standards are light violet-blue and the giant falls rich velvet purple-blue. The texture of the flower is little short of wonderful.

SOUVENIR DE MME. GAUDICHAU (9.3), 15s., is, at its best, my favourite Iris, and (again at its best) I should be inclined to give it a rating of 9.5. Last year, after the fine ripening season of 1921, as I saw it on Messrs. Wallace and Co.'s stand at Vincent Square, no one could convince me there was anything better in the Iris world than *Guadichau*, but it was down to 9 this year, or perhaps even 8.8; but I shall not lose my faith in it. It is not so large as some flowers, yet it seems to have every good point—size enough to shew off its great beauty and wonderful colour; habit of growth, the "carriage" of its blooms, and the form and grace of the flowers leave little to improve upon. The standards are silky violet and the falls deep violet plum. A strong and lovely bit of colouring.

LORD OF JUNE (9.1), 2s. 6d., is deservedly one of the most popular of all, and is probably the most strongly and sweetly scented variety in existence. A flower nobly built on generous lines on a plant of robust habit. *Lord of June* cannot be left out of any collection. The standards erect and well arched, are clear lavender blue and the falls deeper, toning into violet-blue.

ALCAZAR (8.9), 2s. 6d., is another indispensable on account of its fine stature, freedom of flowering, commanding colour and easy growth. Standards reddish violet-blue, falls deep purple with bronze flush. A well grown clump of this makes a splendid picture in the garden.

CRUSADER (8.7), 7s. 6d.—I consider this Iris worth a rating of 9, both by virtue of its clear blue colour tone and the almost perfect form of its falls. In the latter there is a smoothness of texture which will be very difficult to excel in future developments of the flower, and the branching habit of the plant gives plenty of room for each bloom to shew itself to perfection. The colour is an iris blue of the clearest and most beautiful shade.

OPERA (8.7), 3s. 6d.—A distinct variety of rather unusual colouring and very shapely flowers. Standards bronzy purple; falls of velvety appearance, deep red-violet with a blend of orange on the reverse side. Excellent for the front row, as it grows rather dwarf, the spikes rising only about 2ft. 6ins.

ED. MICHEL (8.6), 5s.—This, again, is of a strikingly distinct colour, being almost claret red and practically a "self." The standards are slightly frilled and the falls large and wide, giving the flower an imposing appearance. A great improvement upon *Caprice*, which was formerly looked upon as the best of the red-toned Irises.

ONE OF THE BEST OF THE NEGLECTA SECTION,
IRIS MONSIGNOR.

By kind permission of Messrs. Barr and Sons.

Dominion are bracketed (9.4), and as all are worthy of mention we shall take them in that order.

AMBASSADEUR comes near to being, so far, the perfect garden Iris. Tall and stately, rich in colour and the acme of refinement in form, it is a gem which ought to be in every garden. In colour it is reminiscent both of *Prosper Laugier* and *Alcazar*, but superior to either in every way. The standards are ruddy violet and the falls deep velvety violet purple. The price is about 10s. 6d.

BALLERINE is another tall strong grower of branching habit and a typical pallida. Standards

Afterglow (8.0, 12s. 6d.). I have given this the last place in a dozen very choice varieties because of its exceedingly soft colouring. Both standards and falls are a lightly blended greyish buff with faint lavender flush, shading to rich yellow by the haft, which is reticulated grey-brown. The spikes are well branched and the growth excellent.

It is not easy to mark out any special dozen among the goodly number of great Irises available for selection at the present day. I have purposely avoided many new seedlings now on the market, magnificent specimens of the hybridiser's art, but costly and not yet thoroughly tested in all kinds of soils and climates. Even then, perhaps, I should have given places to Queen Caterina (9.1) of pallida dalmatica type; Shekinah (8.8), the most resplendent of all yellow Irises in the tall growing section; Phyllis Bliss (8.9), in lavender pink, in very fine form this year as shewn me by Mr. Wallace a few days ago at Vincent Square; Magnifica (9.1), a huge violet bicolor of sweetest scent; and Avalon (9.1), a pale mauve of refined form and splendid substance.

Among the older varieties, too, there are many Irises which will still hold their own in the best company, and may safely be planted by those who seek high-class flowers at a moderate price. The following would be a good dozen in varied height and colouring: Isoline (8.6), 2s. 6d., buff pink with russety mauve; Lady Foster (8.8),

5s., a large pale blue veined old gold at the haft, sweetly scented; Monsignor (8.4), 1s. 6d., standards pale violet, falls deeper violet heavily overlaid dark purple, fine rich colour effect; Quaker Lady (8.4), 3s. 6d., a very lovely softly toned flower in smoky lavender, yellow and orange; Erstran (8.2), 3s. 6d., a lovely contrast between the pure white standards and deep purple falls, rather dwarf; Archévéque (8.3), 2s. 6d., also dwarf but conspicuously rich in colour, deep velvety violet and violet-purple; Montezuma (8.3), 5s., old gold stippled with bronze; the base of the falls is almost white with a broad margin of bronzy yellow; Prosper Langier (8.3), 2s. 6d., a popular variety, tall grower with strong, erect stems; standards smoky cinnamon with sheen of pink, falls violet carmine; Azure (8.2), 2s. 6d., a finely toned blue Iris, with lavender shading in the standards and violet in the falls; Dora Longdon (8.1), 5s., standards pale lavender suffused yellow, falls rich reddish violet edged yellow, very free and a pretty Iris; Trojana (8.1), 2s. 6d., a true branching Iris giving this habit to many of the newer seedlings; a stately bicolor of rich reddish violet and purple; Fairy (8.9), 2s. 6d., very tall; medium-sized flowers of creamy white flushed blue in the styles; delicate and sweet; Lorely (7.9), 2s., standards bright primrose, falls dark raisin purple edged yellow; a brightly coloured variety giving a fine effect in the mass.

J. L. GIBSON.

BEARDED IRIS SPECIES

IN this section of the genus *Iris* are to be found many of the most desirable and attractive kinds, useful for the herbaceous border, isolated beds, margins of ponds, as well as irregular groups in open woodland. For the rock garden there are the many forms of *I. pumila* and *I. Chamaeiris*, welcome for their dwarf

habit and early-flowering properties. They are all of easy culture, succeeding and flourishing in a good loamy soil which, if it contains lime, is so much the better for the plants. While many of the larger so-called "German" Irises will in many places flourish and flower freely for many years without being disturbed, they are all benefited

by a periodical lifting and dividing. When this is done the soil should be thoroughly trenched before replanting, adding fresh loam at the same time. There have been many discussions as to the correct time of lifting and replanting these Irises, but when all is said and done there is little in it. A good time is directly after the plants have flowered, carefully selecting the strongest rhizomes for the purpose. If planted firmly and well watered in, they will soon become established and make good growth before the winter. Some will flower the following spring, but, generally, they are at their best during the second season after replanting. We will first deal with the *pumila* section, as this is the earliest to flower.

I. PUMILA.—Of early-flowering Bearded Irises this is one of the most desirable, perhaps the best form being the variety *cerulea*. It is variable in colour, and some other dwarf Irises are frequently grown under this name, but the very short stem and long perianth tube of *I. pumila* distinguishes it from the others. The whole plant is only a few inches high, with stems bearing single flowers of dark lilac or sky blue colouring. The falls are densely bearded and reflexed. It is a native of Central and South-Eastern Europe from Austria to Asia Minor and the Caucasus.

I. CHAMAEIRIS.—This is a much commoner plant than the above, and very variable in colour. In many gardens it does duty for *I. pumila*. It has a stout creeping rhizome with green ensiform leaves 3 ins. to 4 ins. long. The stems of some forms reach a height of 6 ins. and are one-headed, with bright yellow flowers in the typical plant. The falls are 1 in. broad with a dense yellow beard, while the haft is tinged and veined with brown. It is found in Central Europe from Southern France to Dalmatia. The principal varieties are *italica*, with a dark violet limb, in habit like the type; and *olbiensis*, a taller plant, also with dark violet flowers.

Other dwarf Irises include

I. ARENARIA.—This grows in dry sand in Eastern Europe, with much-branched creeping rhizomes and tufts of narrow leaves. The stems are very short and each bears one or two bright yellow flowers. **I. BALKANA** grows about 6 ins. high, with red-purple flowers, the beard of the falls being composed of white hairs. It is a native of the Balkans and flowers in May. **I. EPIFLORA** reaches a height of 1 ft. It has somewhat glaucous leaves and violet-purple flowers, the falls of which have a bright yellow beard. As its name implies, the stems are two-flowered. The fragrant blossoms are produced in April. It is a native of Portugal and Morocco. **I. FLAVISSIMA** is a pretty little Iris with narrow leaves 4 ins. to 5 ins. long, and rich lemon yellow flowers 1½ ins. across. It is a native of Siberia and Mongolia, ascending up to 6,000 ft. elevation in the mountains of Turkestan. This is a very hardy species, of which the var. *Blondvii* is more robust, with broader leaves and larger flowers.

I. LUESCENS is a handsome, easily grown Iris, reaching a height of 1 ft. It has broad, slightly glaucous leaves. The flowers have a bright yellow beard, while the blade is veined with purple. The var. *Statella* is recognised by its pale yellow, almost white flowers, while it usually flowers earlier than the type. Both are excellent garden plants and well worth growing.

THE WHITE IRIS KASHMIRIANA IN ITS KASHMIR HOME.

I. REICHENBACHIANA is allied to the last-mentioned, nearly a foot tall, with slender stems and pale yellow flowers having a bright yellow beard. It is a native of Serbia and flowers in May.

The section *Variegata* contains many charming forms, some of the best of which are:

I. VARIEGATA.—A most variable plant of which there are numerous garden varieties. The wild plant is chiefly found in Austria and Hungary, and has clear yellow standards and falls that are more or less completely covered with dark red brown veins. From this come all the beautiful forms of an infinite range of colour found in gardens, including one that is nearly pure white. Perhaps the finest of all is the "King of Irises," which has falls of a rich mahogany colour that are edged with gold. Another is var. *aurea*, with clear yellow flowers.

I. CENGIALTI.—An elegant plant of dwarf habit with deep sky blue flowers flushed with purple. It comes from Northern Italy. The var. *Loppio* has dark purplish blue flowers.

I. APHYLLA.—This plant has numerous synonyms of which some are *hungarica*, *nudicaulis*, *bohemica* and *furcata*. It grows about 1 ft. high and produces dark lilac flowers, which have a beard of white hairs on the falls. A feature of this plant is that the stem seems to rise naked from the rhizome, and the leaves die off early. It is a native of Eastern Europe from Hungary to the Caucasus.

I. LURIDA.—This has flowers of a dull purple, the lower part of the falls being veined with purple on a yellow ground. It is closely allied to *I. squalens* and *I. sambucina*, and is a native of South-Eastern Europe.

I. BENACENSIS.—This is a beautiful early-flowering plant with purple flowers. The beard is purplish white to half way down the fall, then yellow. It is a native of the Southern Tyrol on calcareous rocks.

Belonging to the *Germanica* group are many important garden plants of great beauty with large, highly coloured flowers.

I. GERMANICA.—This is the commonest of all Irises and one of the most useful. It is found in most cottagers' gardens all over the country, so needs no description, its bright purple flowers with the yellow beard being well known. There are several good garden varieties, including *Sirvas*, with narrower leaves and falls of an indigo purple, while the standards are almost of an Oxford blue; *Amas*, with slightly fragrant flowers of very large size; *alba*, with white flowers; *Kharput*, with rich blue standards and violet-purple falls; and *Purple King*, a rich purple.

I. IMBRICATA (syn. *I. flavescens*) is one of the most distinct, with clear yellow flowers. It grows about 2½ ft. high, with broad leaves, and flowers in May and June. It comes from the Caucasus and Armenia, and is one of the easiest of all to grow.

I. SQUALENS.—This is a taller-growing plant, and as a group contains some of the most richly coloured as well as some of the dullest coloured flowers in the section. In the more typical kinds the upper part of the fall is bright lilac purple, while the claw is veined with lilac-purple on a whitish or yellowish ground. The standards are of a plain dull lilac and yellow or brownish yellow. It comes from Central Europe and extends to the Caucasus. One of the best forms is *Jacquimiana*, with flowers described as a combination of coppery purple and velvety maroon.

I. SAMBUCINA.—The strong scent of Ekler, on account of which the name is given, is characteristic of this plant. It is less robust than the above, with narrower segments to the flower and falls coloured and veined with claret-purple. It is found wild in Central Europe to the Caucasus,

I. KASHMIRIANA.—A sweet-scented not very hardy species from Kashmir, which bears its white flowers in May.

I. NEGLECTA.—A very variable plant of which there are numerous garden varieties. *I. neglecta* is characteristic in having both standards and falls of the same kind of blue, though the former are always of a lighter shade than the latter. Unknown in a wild state.

I. AMENA (syn. *I. hybrida*).—In this the standards are usually pure white, while the falls are of some shade of blue or violet. There are many beautiful varieties, one of which is called *Thorbeck*, with deep velvety violet falls and white standards. In others the falls are veined with some shade of blue or purple on a white ground. One of the best is Mrs. H. Darwin.

I. CYPRIANA.—A native of Cyprus, with tall stems and large, bright lilac flowers in June.

The *pallida* group consists of four well marked kinds:

I. FLORENTINA.—Supposed to be the orris-root of druggists, but it is not the only one that is used. It is a handsome early-flowering plant, very free-growing, with somewhat glaucous foliage and stems 2 ft. or more high. These bear several large

white flowers tinged with lavender and having a bright yellow beard on the falls; a native of Central and Southern Europe. The var. *albicans* comes into flower later than the type, and has almost pure white flowers.

I. PALLIDA.—This is characterised by its broad and very glaucous leaves and tall stems. These are branching and usually have fragrant flowers of a lovely blue lilac shade in the more typical forms. One of the best is var. *dalmatica*, with very large flowers of a deep lavender colour and a bright yellow beard on the falls. Queen of May has flowers of a soft rosy lilac shade. There are numerous other beautiful varieties. The type is a native of South Europe and Western Asia.

I. Plicata.—A distinct kind, marked by having the white falls veined with lilac at the margin and standards also white flushed with violet at the edge. It grows from 2 ft. to 3 ft. high and flowers in June. It is supposed to be a cross between *I. sambucina* and *I. pallida*.

I. SWERTII is closely allied to the above, and is probably derived from the same cross, the only difference being in the colouring of the margin, which in this case is pale pinkish purple instead of violet.

W. L.

IRISES FOR THE WATERSIDE

THESE are but two species of *Iris* which are really aquatic, our own native *Flag*, *Iris Pseudacorus*, and its American cousin, *I. versicolor*. This New World *Flag* is variable in colour, but always some tone of purple, either reddish or bluish. Neither of these aquatic Irises is specially free to flower, albeit some strains are freer than others, nor do they lift their flowers quite clear of the foliage, but they certainly add dignity to the pond margin with their handsome spear-like foliage. It is important, moreover, to select the best forms, for some forms of *Pseudacorus* are much more prolific in blossom than others; while there is a very attractive pale primrose form, generally listed as *Bastardi*. The reddish form

of *I. versicolor* is called *Kermesiana*, but the best blue-purple forms are equally lovely.

Granted that the two species mentioned are the only true aquatics, there are other kinds which do not object to winter flooding—some of them, at any rate, appreciate it. Most noteworthy of these is the Siberian *Iris*, *I. sibirica*, which, in good forms at least, bears its flowers in quite remarkable profusion on 4 ft. tall hollow stems well above the foliage. The writer considers this the handsomest of Irises, but not everyone would agree with him, of course. It is not absolutely necessary to grow this plant in wet ground—it will hold its own in the herbaceous border—but those who only know it under such conditions are not competent to speak of its worth. The

THE STately IRIS SIBIRICA BY THE POOL-SIDE.

best form of colour and form, but there is now a form called Perry's Blue which is probably the nearest to a true blue to be found in the genus Iris, for it is worthy of note that, while blue in some shade and combination is the commonest of colours with this genus, it appears always to be mixed to greater or smaller degree with red. In all the race of Bearded Irises, species and hybrids, there is not one which approaches pure blue, and the same may be said of the winter-flowering *I. unguicularis* and related species, and of the gorgeous *Krempferi* forms, upon which the Japanese have lavished so much skill and care. To return, however, to *I. sibirica*, there is a white form often offered in nurserymen's lists which is only mentioned here to warn readers that it is dingy in colour and has nothing to recommend it.

I. orientalis is an allied species no doubt, but it is unfortunate that catalogues often list it as a form of *sibirica*. From a garden point of view it is entirely distinct, and, it must be admitted, much less valuable. The flowers, individually, are larger, but borne less freely on the spathe, while the spathes themselves are scarcely so freely produced. It loses ground principally though in the fact that the blossoms scarcely appear above the tops of the "grass," which is a little lusher than is the case with the more western species. In most forms of this Iris the spathes are tinged with red. An excellent form in which the spathe colour is particularly bright is listed as var. *saugunea*. Perhaps the most valuable form of this plant, however, is the albino usually listed as Snow Queen. This is large and of good form and, though not a

dear plant, is of considerable pleasing and. It associates especially well with the richly coloured form of *I. sibirica* and blossoms at the same period.

A new species from Western China, *I. Wilson*, bears much the same relation to *I. sibirica* that *Primula Bulleyana* bears to *P. japonica*; that is to say, it is, for garden purposes at any rate, practically a colour form of the older species. Unfortunately, *I. Wilson* lacks the rich colouring which made Bulley's *Primula* so much appreciated; the flowers are soft yellow, a colour usually very effective in the garden, but in this case hardly strong enough for the size of the flower. Another yellow species belonging to this section is *I. Forrestii*, which in habit of growth is not unlike a dwarf *I. orientalis*. The yellow here has more body. It is a pity that *I. Wilson* does not combine this colouring with its own more graceful habit of growth, but perhaps the hybridist will put things right. The drawback is that no artist with the pollen-brush can produce a species, and some of us, at any rate, feel differently towards a genuine species than we do towards any garden plant, however splendid.

Yet another of the *sibirica* clan is *I. Delavayi*, to which moisture is even more necessary than to any of its relatives. This grows about the same height as *I. sibirica*, and the flowers are deep purple conspicuously blotched with white. As with the last-named species the flowers are decidedly on the small side. Besides these we have the American *I. prismatica* with small purple *sibirica*-like flowers and the Himalayan *I. Clarkei* with solid stems and flowers of various shades

of purplish blue. Neither of these species is often seen in garden.

Two very similar species as growing are *I. aurea* and *scholastica*, the former with bright yellow flowers and the latter with blossoms shading from clear yellow at the centre to white at the edges. Both are excellent border plants, but both give of their best when granted bountiful supplies of water at the root. They are thus first rate for waterside planting where flooding is not to be feared. A hybrid between these two species is perhaps a better garden plant than either, being freer to flower. These Irises would be worth growing, however, even if they never flowered, for their truly magnificent foliage. *I. Monnieri*, a species (?) of uncertain origin, has blossoms of a beautiful deep lemon shade and a habit of growth very similar to that of the two species previously mentioned. A form intermediate between this and *I. aurea* is listed as *I. Mon-aurea*.

All this about waterside Irises, and nothing about the gorgeous Japanese Flags! Perhaps the writer is saving up the best till the last? Well, that is hardly the case. The fact is the very numerous Japanese garden forms of *Iris Krempferi* will not tolerate marshy ground. It is true that they are impatient of drought; nevertheless, they are very far removed from being bog plants. A really well cultivated herbaceous border suits them as well as anywhere, but they may of course be used—and used very effectively—by waterside if care is taken to see that the soil in which they are to grow is perfectly sweet and will remain so. No doubt for this reason, winter flooding is very

THE SLENDER-GROWING "PINK" VARIETY MRS. J. STERN.
Spike kindly supplied by Mr. Amos Perry.

THE SPLENDID NEW "DOMINION," BERTRAND.
The sensation of the Orpington Nurseries' Stand at Chelsea.

inimical to them. There is quite an extensive range of colour in these flowers and it is best, undoubtedly, to select one's varieties when in flower. Present-day taste leads further and further from the rather bloated double forms so beloved of the Japanese, but these make, at any rate, bold splashes of colour.

Just as the popular imagination has invested Iris Kämpferi with bog-loving attributes quite alien to the plant, so has it overlooked the fact that there is a moisture-loving bulbous Iris. Iris xiphoides, the miscalled English Iris, is never

so happy as when growing in stiff, rather cold and wet soils. Indeed, it will stand winter flooding which would be fatal to the Kämpferi forms. The English Iris has of late been out of fashion and it is now not at all easy to procure bright self-coloured "unbroken" varieties. Let us hope that some of the hybridists may quickly take it in hand again, for it might easily be made quite as effective as any Kämpferi variety can be, and it has a great advantage in being bulbous. It is such a simple matter to people the earth with bulbous plants!

made of recent years with these Bearded Irises is from one point of view very marked, from another view point it is less remarkable. Let us take three old natural varieties—*pallida*, *dalmatica*, and the *germanica* forms *Annis* and *Kharput*—and set beside them modern sorts of similar colouring. Have we advanced so far after all? From another point of view let us review all the pure white and golden yellow June-flowering sorts and decide if we feel proud of them!

Yet, of course, there has been immense progress (especially if we do not adopt the American standpoint), and greater progress may be expected in the near future. The gold and carmine *Citronella*, certificated last year, is a beautiful thing, so, in quite a different way, is the sort certificated as *ochracea* *corulea* but now usually listed as *Sunset*. Even more noteworthy than these is Mr. Dykes' *Thundercloud* (certificated recently), which bears its violet-coloured blossoms with splendid freedom. This is not a large flower, however, and will make small appeal "across the pond," unless for breeding purposes, yet English raisers are to the fore with varieties which suit the New World market. There are, for example, such sorts of *Dominion* type as *Duke of Bedford*, so well shewn at the Iris Show last year, and *Bertrand*, illustrated herewith, one of Mr. Bliss's handsome productions. The flowers are very large even for a "Dominion," it is a tall grower (3½ ft.), the "grass" is handsome, and the flowers are a study of shades of lavender and violet, quite distinct from all others of the *Dominion* race. Such a beauty must have a certain following "on this side"; it is certain "over there" to be a "best seller."

Great improvements have been effected among the "pink" *pallida* varieties, and greater still are in store. Among those in commerce the splendid *Aphrodite*, yet another of Mr. Dykes' seedlings, is one of the brightest and best. It is tall and shapely, and its colouring, if not pink, is very much brighter than that of most "pink" sorts. Another excellent "pink" sort is the rather early-flowering Mrs. J. Stern, a slighter grower altogether, with standards noticeably lighter than the falls.

It must never be overlooked that in the *pallida* section we had practically everything but an extensive colour range to start with. Such is not the case with the *variegatas*, for example. Unquestionably *Iris König* is a great improvement upon the older forms, but there is still room for many good new varieties.

The *pallida* varieties as collected are quite up to the average in freedom to flower—at least on moist soils—but some of the products of the breeder's art in this section are much superior in this respect. The rather small-flowered *Corida* has been noted in this connexion. Another very free-flowering sort is the quite new *Eden Phillpotts*, one of Mr. Amos Perry's seedlings (and a very fine one) of *pallida* × *Cengialti* parentage. It is a self of rather dark lavender blue colouring and the flowers, which are produced on branching stems, of great size.

From the same raiser Lord Lambourne is another very noteworthy sort which found many admirers at this year's Chelsea Show. The flower is large and shapely, and the reticulation on the falls very handsome. The colouring is a little difficult. On the whole, probably, the raiser's description can hardly be bettered: "Standards rose-fawn, suffused pale bronze, falls rich madder crimson with a bold white reticulated base, illuminated with a brilliant yellow beard." This is a tall, strong grower.

Another tall sort and an equally strong grower is *George Yeld*, named in honour of the president of the British Iris Society. This is a particularly graceful variety, the arrangement of the blossoms

WHITHER?

Under the above heading the Editor discusses present-day tendencies in Iris breeding.

THE immediate future of the Iris concerns itself almost entirely with the Bearded sorts, for while some raisers—Mr. W. R. Dykes, for instance—have laboured hard at the *Apogon* Irises, crossing them not only with one another, but also with Bearded kinds, the great garden-loving public on both sides of the Atlantic takes little interest in any Iris outside the range of what the "man in the street" calls "German" sorts. Again because, on the average, they are taller and more handsome and also, no doubt, because they flower at a season when they are particularly welcome, the June-flowering varieties have a big pull in the race for popularity over those which flower earlier.

Readers will notice that Mr. J. L. Gibson on another page weighs some outstanding varieties in the balance of American opinion. With due respect to Mr. Gibson, who is, of course, a recognised authority, it seems to us that an American judgment on an Iris "cuts no ice"—to use their own phrase—in this country. To see Mr. Wister, the president of the American Iris Society, and some of his enthusiastic colleagues inspecting a collection of Irises is to realise very quickly that in America the Iris is just as much a Florist's flower (capital F, Mr. Printer!) as at one time the laced Pink was here.

Colouring, as such, is of little account, though the amount of reticulation on the falls is a point: form (above everything) and size are the great criteria. Form is judged—at least so it seems to the writer—from the point of view of an arbitrary standard, just as one judges the points of a Leghorn or Wyandotte fowl, for instance, and as regards size the American Iris fancier—fancier is the right word in this connexion—has no use for a good "little 'un."

Now, the Iris has not yet become a fancier's flower in Great Britain and, personally, we hope it never may; consequently, some varieties which are assured of popularity in this country will never gain favour in the United States of America, and, conversely, certain varieties which have received good marks in the American symposium are destined never to become popular in Britain.

Two of the finest Irises from an American point of view are *Alcazar* and *Dominion*. Many people,

PERHAPS THE BRIGHTEST OF "PINK" IRISES, THE TALL AND STATELY APHRODITE.

while admiring the carriage and colouring of *Alcazar*, cannot appreciate its form, particularly as regards the falls. No one will deny the beautiful shape of *Dominion*, but who would consider it free-flowering? and surely freedom to flower is a great point—an essential point we should say—of any border plant. It would be a thousand pities to let the splendid form of *Dominion* be lost, but its main value—or so it seems to us—lies in its usefulness to the hybridist.

It is always difficult to name one's favourite variety of any flower, but among Bearded Irises the writer's favourite is certainly the small-flowered *pallida* *Corida*, which bears shapely spikes of nicely formed and well poised flowers in the greatest profusion. The progress that has been

on the much branched stem being particularly good. The standards are bright apricot with rose shading, and the falls crimson, edged buff,

the white reticulation bold without being heavy, the beard orange. Mr. Perry introduced many years ago the now well known and late-flowering

Black Prince. It is shapely and free-flowering, the standards lavender and the falls black violet, cleanly edged with pale violet.

LATE-FLOWERING AZALEAS

BECAUSE they are unable from a botanical standpoint to separate Azaleas and Rhododendrons, botanists include them all in the genus Rhododendron. The original broad distinction was the evergreen Rhododendron with ten stamens and the deciduous Azalea with five stamens. When species were introduced with these characters reversed or which did not fall into either group,

there was nothing to do but sink one of the names in the herbarium. The popular name of Azalea will always, we must hope, be retained to indicate the most beautiful family of hardy deciduous flowering shrubs cultivated in our gardens.

Most of the varieties are at their best from late April to early in June, with a wonderful wealth of blossoms during May. These notes are intended

to draw attention to the possibilities of a race equally rich in colours, flowering from mid-June and throughout July. We already have several species flowering at this season, beautiful in themselves and with a delicious fragrance, but they lack the rich and varied shades of colour so charming in the spring and early summer-flowering hybrids. Some crossing has been done with these species already, and especially with *R. occidentale*, but the hybrids invariably flower in advance of the species, which is only natural when an early-flowering pollen-parent is used. To obtain the object in view, breeding must be systematically focussed on the raising of seedlings, and the crossing of the latest to flower, for several generations.

The one thing we may be "up against" in the raising of a race of late-flowering Azaleas is that they will be at their best during the hottest weeks of the year. We know, however, that the wild Azaleas grow in shady, damp situations, and we should do well to follow Nature more in our planting. The Cornish growers may have an ideal climate for Rhododendrons, which is half the battle, but they are also fully alive to the value of mulching. Here again we should copy Nature by mulching annually with leaves, using sticks to hold them in position. Rhododendrons and Azaleas are surface-rooting, with fine roots which drought will soon kill. Leaves keep the surface cool and moist in summer and warm in winter.

A peaty soil is by no means essential, for Azaleas thrive in a moist, loamy soil that is free from lime. Hard or close ground can soon be brought into condition by trenching and adding plenty of leaf-mould. While named sorts must be increased by layering, cuttings or grafting, the species can be freely raised from seeds. Much more should be done in the raising of seedlings from hybrids for woodland planting. The probability is, in such case, that these will give a wide variety, while there is always the possibility of something even better than the named parent plant.

RHODODENDRON OCCIDENTALE.—This species was first introduced from Western North America, about the middle of last century, by William Lobb when collecting on behalf of Messrs. Veitch. It is the best of the late-flowering section, being at its best about Midsummer Day and lasting well into July. For planting in open woodland with, possibly, a running stream we can scarcely wish for anything better. There are forms with white flowers and a yellow blotch, and others of pleasing pink shades. The deepest form at Kew is labelled *R. occidentale* var. *roseum*. By crossing this species with some of the earlier-flowering section Mr. Anthony Waterer has raised a number of hybrids with light-coloured blossoms. The best of these we have grown are *Exquisite*, *superba*, *gaucosa*, *delicatissima* and *magnifica*. Whether there is any *R. occidentale* blood in the richly coloured *Knap Hill Scarlet* I do not know. One thing we may safely assume is that flowering during the second half of June, it will be a useful plant for hybridising with the light-coloured species. *Davisi*, the popular variety with cream-coloured flowers often grown in pots for forcing, is one of the first *R. occidentale* hybrids.

Not the least desirable character of *R. occidentale* is that flowers and foliage develop together, and added to this is a delicious fragrance. Eight to

THE FLAME-COLOURED RHODODENDRON CALENDULACEUM.

THE WHITE-FLOWERED "SWAMP HONEYSUCKLE," RHODODENDRON VISCOSUM.

ten feet appears to be the ultimate average height of large bushes.

R. viscosum.—The white Swamp Honeysuckle is one of the last of the deciduous Azaleas to flower. Commencing in late June, the bushes blossom throughout July, the flowering period

white blossoms freely stained with purplish lilac. Raised about one hundred years ago, this is the *R. fragrans* of Paxton, *R. odoratum* of Loddiges, and in nurseries is often grown as *Azalea odorata*. The latter name is most appropriate, for it is certainly one of our most fragrant hardy shrubs.

THE WHITE-FLOWERED FORM OF RHODODENDRON OCCIDENTALE.

even extending into August in late districts. The flowers being among the smallest of the Azalea family, the name of Swamp Honeysuckle is most appropriate for this species. The colour varies from white to those with buds and blossoms daintily tinted with pink. The delicious fragrance appeals particularly to ladies, and when this species is planted in sufficient quantity the scent is powerful enough to pervade the air.

R. viscosum was first introduced from Eastern North America in 1734. As a wild bush it favours the moist ground and swamps of Maine and Kentucky, its distribution extending from Canada to the Southern United States. Young plants commence flowering when 1 ft. high and blossom each year with unerring freedom until the twiggy bushes are 6 ft. to 8 ft. or even 10 ft. in height. The viscid or clammy character of the flowers is more pronounced in this species than in any other species of the American group.

The old florists are reputed to have used this species freely in raising the hybrid Azaleas of the first half of the nineteenth century, but in the desire for large flowers more attention has been given to *R. molle* and *R. sinense* as parents, with the unfortunate loss of much of the pleasing fragrance. Some of the oldest bushes in the Azalea Garden at Kew in the white, pink and rose tints of the flowers, fragrance and viscid character suggest *R. viscosum* as one of the parents.

R. viscosum VAR. *GLAUCUM* (*Azalea glauca* of the old florists) in its best forms is a pleasing shrub with a silvery sheen to the foliage, the under-surface being blue-white. The best known hybrid of *R. viscosum* is *R. azaleoides*; the other parent is said to be *R. maximum*. It is evergreen or semi-evergreen in character, very free and bushy in growth up to 5 ft. or 6 ft. in height and more in diameter. The flowering season is June and early July, when the bushes are crowded with

It is one of the easiest Rhododendrons I know to root from cuttings during late summer.

R. CALENDULACEUM is the Flame-coloured Azalea of Eastern North America. It is a widely distributed species, and variable in the colour of the flowers (red, orange and yellow) and the season of flowering. This is the species from which the rich colouring in many of the Ghent Azaleas was obtained. The early flowering of these hybrids suggests that the *R. calendulaceum* used was the form flowering in May or early June. Seedlings of more recent introduction are at their best about the middle of June. With their rich orange-coloured flowers this form should be a valuable one to cross with *RR. viscosum* and *occidentale*.

A. O.

MORE ABOUT THE GREAT ROSE SHOW

(Continued from page 345)

THE lack of exhibits was, naturally, more pronounced in the amateurs' classes than in the trade section. Few amateur rosarians grow anything like the maximum number of plants permitted by the rules for the various divisions. Consequently, as they have only comparatively few plants to cut their blooms from, such a very adverse season has even more harmful effects than with the trade grower. But in spite of this and with the full knowledge that their blooms were often of such second-rate quality that in an ordinary season they would scarcely have been placed in a vase for the sitting-room, the amateurs rose nobly to the occasion and, rather than "let the Society down," brought what they had. As the

day wore on it must have been with pleasurable feelings that these high-spirited exhibitors saw their blooms, under the influence of the genial warmth, gradually expand, disclosing unsuspected beauties and value.

Yet one missed the names of some of the prize-winning exhibitors of former years. With exhibition Roses Mr. W. J. Bambridge (Kettering), Mr. F. H. Fulgate (Colchester), Dr. F. G. Hayes, Mr. H. Amos, Mr. J. C. Wiseman, Mr. G. Marriott, Mr. F. Slaughter, Mr. H. N. Rogers and the Rev. R. Burnside all shewed blooms that did them credit. These names are not placed in any order of merit but as characteristic of the first prize winners. In other classes premier honours were taken by Mr. H. R. Darlington, Mr. J. J. Williamson, Mr. S. W. Burgess, Mr. F. H. Fulgate, Mr. W. J. Green, Mr. W. E. Moore and Mr. M. H. Ward, and they also shewed blooms which compared very favourably with those of the trade growers.

The vases and stands in the tent for decorations with the Roses were all splendid from the rosarians as well as the decorator's point of view. Nearly all the blooms had the imprint of glass-house culture, but they were charmingly fresh and beautiful. In the open class the best table was that of Mme. Butterfly arranged by Mrs. A. R. Bide. In the amateurs' classes Mrs. Courtney Page was very successful, and displayed especial taste in her arrangements. In the class for single Roses she used Irish Elegance. In the other Mme. Butterfly was the variety, and in both cases the flowers were arranged with consummate skill. The dinner-table class, which requires the flowers to be grown by the exhibitor, must have given the judges considerable trouble, and they awarded the first prize to Mrs. H. Barton, who associated Emma Wight with Old Gold; while Mrs. Courtney Page, who was placed second, used Sunstar, Ethel James and Isobel. Both were very charming tables. Mme. Butterfly was largely used in the bowls and vases arranged for effect. Mrs. Bide in the open class and Mrs. Courtney Page in the amateurs' were the most successful exhibitors.

The usual silver medals were awarded to the premier blooms of the various sections. The medal blooms in the amateurs' classes were Frau Karl Druschki (H.P.), shewn by Dr. F. G. Hayes; Mrs. E. J. Hudson (H.T.), by Mr. W. E. Moore; and White Maman Cochet (T.), by Mrs. F. Pridham.

Many non-competitive exhibits added to the attraction of the Show. Messrs. William Cutbush and Sons arranged a very beautiful group of standard and dwarf cluster Roses in pots. Mr. J. C. Allgrove brought many well flowered sprays of *Rosa Fargesii* and *R. Moyesii*.

Apart from the Roses there were many interesting exhibits of other flowers and horticultural appliances on view in the Palm House and in close proximity to it.

Messrs. Blackmore and Langdon brought up a very representative collection of their magnificent Delphiniums. Near by Mr. William Vandell of Maidenhead shewed a goodly collection of Violas. Saxifraga Tumbling Waters was again well shewn by Captain Symons-Jenne, while Messrs. J. Cheal and Sons had on view their admirable Star Dahlias. These varieties are excellent for cutting purposes and, unlike some of their "elders," are not susceptible to the ravages of earwigs. Peonies and Delphiniums in many shades were admirably displayed by Messrs. R. H. Bath, Limited, of Wisbech.

Messrs. Allwood Brothers had two exhibits, one being just outside the Palm House. Here, as in their other exhibit, they shewed a representative collection of Perpetual-flowering and Perpetual Border Carnations and Allwoodii.

Sweet Peas were well shown by Messrs. Dobbs and Co. and Messrs. Andrew Ireland and Hitchcock. Mesembryanthemums, Campanulas, Primulas and well flowered plants of *Nierembergia rivularis* were put up by Messrs. Maxwell and Beale of Broadstone. Mr. C. Engelmann had a fine collection of Carnations, among which Lady Northcliffe, Tarzan, Laddie, Thor and Cree were conspicuous.

Mr. Ernest Dixon shewed a model garden which deservedly attracted a great deal of attention. Outside Mr. Dixon had, in conjunction with the Rural Industries, Limited, of Cheltenham, some excellent garden furniture, which, by the way, is English made. The chairs are exceptionally comfortable, and the writer took the opportunity—during Mr. Dixon's absence—of writing these notes at the exhibit. Not far away the House and Garden Sundries Company, Limited, shewed an excellent garden hammock and stand. Here, again, we had a rest—in fact, we had quite an enjoyable day! The combination has many advantages. It is, for example, exceedingly useful for those who do not possess trees in their garden; it also folds up into a very small space. This firm also shewed and demonstrated their "Everyman's" patent straining wire.

Mr. Haws of Clapton shewed capital watering cans in all shapes and sizes, and Messrs. Abol, Limited, shewed and demonstrated their world-famed syringes. They also shewed insecticides and fertilisers. Mr. H. J. Greenwood of Bracknall displayed the Willmott plant stakes, which hold securely all kinds of plants without tying.

Messrs. Maurice Prichard and Sons of Christchurch had a fine lot of their single and double-flowered *Dianthus Prichardii*. Messrs. Carter Page and Co. shewed Dahlias of all sections and also had a small rockery.

Delphiniums, Pæonies, Irises, Columbines, Campanulas, Sunbeam Poppies, Pyrethrums and a host of other hardy plants were shewn by Messrs. George Bunyard and Co. of Madstone.

The Cross Bone Manure and Lime Company, Limited, of Bridlington shewed artificial manures.

Messrs. Shanks shewed and demonstrated their well known mowing machines, as also did Messrs. Ransomes, Sims and Jelferies. Messrs. Jeyes' exhibited their famous horticultural washes.

Messrs. Hawker and Botwood, Limited, of Grays, Essex, exhibited their well known non-poisonous insecticide and fungicide, which they have so aptly named "Sox." Here, too, were to be seen Dyoweed, a *non-arsenical* weed-killer; "Maskris," a natural organic manure claimed to be a most effective substitute for stable manure; and Prize Crop, the well known fertiliser.

In last week's report, a new crimson single Rose from Messrs. D. Prior and Son was inadvertently referred to as *L'equus*, the name of another single variety already in commerce. The one exhibited by Messrs. Prior is named *Etna*.

THE ENKIANTHUS.

A FLAT, horizontally spreading system of branching, similar to that of the Cedar, is very characteristic of many trees and shrubs in Japan. It is a type of growth much beloved of the Japanese artist, as one may see on many a screen and fan. *Enkianthus campanulatus*, introduced from Japan in 1880, has this mode of branching, and is a shrub 4 feet to 6 feet high, sometimes more. Its greatest charm in the garden is the rich crimson hue of its leaves in autumn. The bell-shaped flowers are elegantly disposed and of a pale creamy yellow veined and tipped with red. It belongs to the Ericaceæ, or Heath family, and like most of its allies enjoys a peaty soil, or, failing that, an open foam with plenty of leaf-soil added.

CORRESPONDENCE

OUR WATER LILY FLOWERS IN WATER.

HOW should the above be treated in order to prevent them from shutting up in the evening and usually not opening or only partially opening again the next day? Should the flower be picked when in full bloom and when fully expanded by the sun, or otherwise? I find that different sorts of Lilies behave differently.—B.

The difficulty in question was submitted to two well known experts, and their replies are given below.—ED.]

THE cause of the Water Lilies refusing to open is that the flowers partly close at sunset, lose their equilibrium and become water-logged. The best way to prevent this is to have the flowers removed at the end of the day, lay them on a moist cloth and replace next morning. If the flowers become too rigid and there is a difficulty

and under glass Water Lilies must be grown fully exposed to sunshine. *Victoria regia* opens its flowers only at night; so it is difficult to get over these hereditary habits.—HORTULANUS.

MIMULUS BARTONIANUS.

THIS splendid *Mimulus* was raised some years ago by Mr. H. O. Barton of Co. Antrim, its parents being, I believe, *M. cardinalis* and *M. lewisii*. In cool, good soil this plant will attain the height of 3ft., that in the accompanying illustration just managing to peep over the rim of the 40-gallon water-butt. The foliage of *M. Bartonianus* is a darker green than that of most of its race, the deeply veined leaves and stems being slightly silvered with hairs and sticky to the touch. The first blossoms usually appear here in early June, that is, when the plant is about one-third of its usual stature, and they are about 2ins. across and very attractive in their

MIMULUS BARTONIANUS, ROSEY CERISE WITH A YELLOW THROAT.

in opening, place them in tepid water. With care Nymphaeas can be kept from ten to twelve days when out.—AMOS PERRY.

INVESTIGATIONS in the past and again recently on the opening and closing of Water Lily flowers shew that it is due to the action of sunlight, and the absence of sunlight respectively. The common white Water Lily opens at 5 a.m. at Upsala, Sweden, but not until between 7 a.m. and 8 a.m. at Innsbruck, Austria; and in both cases this coincides with the shining of the rising sun upon them. The flowers close at 5 p.m. at Upsala, and between 7 p.m. and 8 p.m. at Innsbruck. This is due to the fact that the sun rises earlier at Upsala than at Innsbruck, during the flowering season. The flowers never open at exhibitions unless the sun shines upon them, though the exhibitors may be expert growers. If the flowers are out while open they can certainly be enjoyed for a time, but they should be as fully exposed to sunshine as circumstances permit. Tepid water might delay their closing towards the end of the day. Outdoors

bright rosey cerise with a distinct yellow throat. Flowering continues with great abundance throughout the later summer and often well into autumn, when the plant dies back to the base. *M. Bartonianus* is said to be quite hardy at Edinburgh, and here it is a robust and long-lived plant. Propagation may be carried out by striking cuttings in early autumn.—A. T. J., North Wales.

STRAWBERRY CULTURE.

ON page 324 in the issue for June 23 it is stated that "old Strawberry-beds are never profitable." I should like to say that this year, in spite of the exceptionally gloomy season, our Strawberries (Royal Sovereign), which were put down five years ago, have produced a record crop of very fine berries and the plants are better than they have ever been. We have been eating the berries for the last week, and yesterday (June 27) we picked 17lb. and there are still plenty to come, so we have been more fortunate than our neighbours with large gardens. The soil here is very light and sandy.—W. R. OGILVIE-GRANT.

THE CAMASSIAS.

I WAS much interested in the letter of "J. J." in your issue of June 30 on the Camassias. I myself have a cream-coloured variety (or ? separate species) which grows about 3 ft. high and has large flowers. It was among a "mixed" collection from Messrs. Barr's, but all the others were a small pale mauvy blue, probably *Cusickii*. I have some seedlings from both of these kinds, and I should be interested to learn how many years they are likely to take before flowering.—L. H. Cox.

PLANTS WITH LEGENDS.

I SHALL be so glad if you will help me in the making of a garden of flower legends, each plant to have its own legend or to be introduced in a legend or be known on account of its medicinal properties in olden days. I have the legends of the following: *Hypericum*, *Myrrhis odorata*, Christmas Rose, *Veronica*, Pansy, *Myosotis*, *Galium*, *Verbena* and *Nicotiana*.—AN OLD SUBSCRIBER.

[The Daisy has a legend. According to Celtic belief each child that is carried back to God by the Angel Death throws down on earth some new and lovely flower. While Malvina was weeping for her child the maids of Morven came running to her calling "Malvina; oh, Malvina! we have seen the infant whom you mourn," and presented her with a Daisy. Do not forget the legend of Narcissus. Many legends

are woven round the Rose. A very old one is that the Arabs believe the first Rose to have sprung from a drop of sweat from the brow of Mahomet. A Christian legend is that it "had its origin in the terrestrial Paradise." The white Rose belonged to Harpocrates, the God of Silence. It became the emblem of secrecy, and was suspended over the guest table, so that confidential talk should not be divulged; hence the saying *sub rosa*. The early Christian Church dedicated the white Lily to the Virgin Mary as an emblem of moral beauty and purity; hence the name Madonna Lily. While Eve sat weeping for the lost Paradise, and nothing but snow had fallen since then, an angel came to earth to comfort her and, breathing on a snowflake, caused it to fall to earth a living flower, the Snowdrop. The above are a few, but many other legends exist. Some of the medicinal plants of olden times and many of the present are the Dandelion (*Taraxacum*), Balm (*Melissa officinalis*), *Mentha piperita officinalis*, *Betonica officinalis*, Borage (*Borago officinalis*), *Paeonia officinalis* (Common Peony), Milfoil (*Achillea Millefolium*), Marsh Mallow (*Althaea officinalis*), Foxglove (*Digitalis purpurea*), Goat's Rue (*Galega officinalis*), Spearmint (*Mentha viridis*), Pennyroyal (*Mentha Pulegium*), Lungwort (*Pulmonaria officinalis*), Sage (*Salvia officinalis*), Winter Savory (*Satureia montana*), Meadow Sweet (*Spiraea Ulmaria*), Common Thyme (*Thymus vulgaris*), Lemon Thyme (*T. citriodorus*), Angelica (*Archangelica officinalis*). etc.—ED.]

trees. As a rule it is the tips of the young growths that become infested with aphids and, in most instances, it is an easy matter to dip them, using a small vessel containing a solution of insecticide. Afterwards well wash the trees with clear water.

Fruits Under Glass.

Peaches.—Trees that are planted out in the houses and from which the fruit has been gathered ought not to be neglected but every inducement given them for the wood to become thoroughly ripened. To this end the ventilators should be opened to their fullest extent both night and day and, whenever the weather is fine, the foliage may be syringed twice each day. The border should on no account be allowed to become dry. If the trees are infested with red spider, they should be thoroughly cleansed with an insecticide.

Vegetables Under Glass.

Tomatoes are producing heavy crops and the roots should be fed with liquid manure and *Le Fructeur*. All side growths should be removed. At this stage the white fly appears and, unless it is held in check, the plants and fruit present a sorry sight. Syringing with XL All insecticide will destroy them, and there are some excellent fumigants available which are especially destructive to white fly.

T. W. BRISCOE

(Gardener to W. K. Lysaght, Esq.),
Castelford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Lettuce.—Make a rather extensive sowing, as by the time the plants are fit for use they will keep longer in good condition than those maturing during the summer months. Continue to make weekly sowings of Mustard and Cress, and sowings of Radishes every ten days. Tie up Cos Lettuces as they develop.

Brassicas.—Draw some earth up to the various members of this tribe which were planted out last month. Where there is a glut of Cauliflowers fit for use they will keep in good condition for a considerable time if they are cut promptly and stood on their bases in a flat vessel containing 2 ins. of water plus a pinch of salt. The vessel should be stood in a cool place where the sun's rays do not penetrate.

Marrows.—Continue to thin and regulate the shoots, stopping any of the main ones that threaten to get out of bounds. Impollinate, about midday, the female blossoms as they open. As stems, foliage and fruits are largely composed of water, copious supplies should be given should a spell of drought set in.

General Work.—Keep crops free from weeds by the use of the Dutch hoe between the rows and by hand weeding in the rows. Do not allow crops—especially Peas—to suffer from lack of water, but beware of the dribble system, which does more harm than good. Thin later sowings of Turnips as they develop.

Fruits Under Glass.

Melons.—Provision should be made for maintaining an adequate temperature where Melons are being cultivated in frames or hotbeds. This is done by using what are popularly known as "linings," which means that the entire hotbed is surrounded by an additional 18 ins. of fermenting material. This is sometimes composed of grass mowings, but they are less satisfactory than the ordinary mixture of stable manure and last season's leaves in equal proportions. These materials should be loosely formed into a conical heap, and when they begin to generate steam should be moved, and re-formed into a similar heap. When they again become heated they should be applied to the hotbed, beating them firmly with the back of the fork.

Peaches and Nectarines should receive close attention as the fruits begin to ripen, and should be picked just as they part easily from the tree. The fruits must be carefully handled, as they are very easily damaged. However, despite the closest attention, a certain number of fruits will fall of their own accord. To meet this contingency a herring net or other small mesh net should be arranged pocketwise under the trees to intercept the falling fruits.

Late Vines.—The berries will now have almost or altogether attained to full size, so within the next fortnight the border should receive a liberal supply of water, after which it will be advisable to cover it with a layer of clean wheat straw to prevent too rapid evaporation. It is not advisable to give another watering until the crop has been

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Turnips.—A good breadth of this useful winter vegetable should be sown in lines 12 ins. to 15 ins. apart, and, later, the seedlings thinned to 6 ins. or 8 ins. Good varieties are Golden Ball and Greentop White; the latter should be chosen if only one kind is grown. Look out for the fly, and as prevention is better than cure, the lines may be dusted with lime and soot occasionally. This operation should also be carried out directly the seedlings are expected to appear. The work is best done early in the morning while the dew is still on the plants.

Shallots are fast approaching the ripening stage and, when the foliage shows signs of maturity, the bulbs should be lifted. If the weather is wet, the ripening process can be completed in a dry, airy shed, or the bulbs may be laid on mats and placed in full sunshine whenever possible.

Leeks growing in trenches will need assistance if the weather proves dry and a sprinkling of soot will be beneficial if applied during showery weather, or previous to watering the plants. Another batch may be planted out to furnish a supply next spring.

Peas.—A sowing of an early variety, such as Gradus, Pioneer and Chelsea Gem, will be found very useful for a late supply—and during the last few years late Peas have been very successful in this district. The late variety Autocrat has also given excellent results. Continue to stake other lines of Peas when they are well through the soil and give a mulching of manure, or grass from the lawns, if a spell of dry weather sets in. Plants producing a crop should be kept moist at the root.

Herbs.—If dried herbs are needed, advantage should be taken of any that have made sufficient growth, which may be cut and dried in the sun or shed. Both methods give good results.

Tomatoes.—Keep these to a single stem, and when three trusses of fruit are set pinch out the top of the plant. Give a mulch of rotten manure and keep the roots supplied with water.

The Flower Garden.

Pinks.—If fine flowers are required, a young, healthy stock should be maintained, and to this end a few cuttings should be inserted annually. Young shoots pulled off with a heel make excellent cuttings, but a few of the lower leaves should be removed. A large percentage would form roots

outside, but for the choicer alpine varieties a cold frame should be chosen, placing a few inches of gritty soil in the bottom. If it is possible lightly to syringe the cuttings three or four times a day when the sun is hot, no shade is needed and little air need be admitted. Otherwise, the lights should be covered with a thin canvas and the soil prevented from becoming dry by an occasional sprinkling of water through a fine rose can. Watch for damp and, if present, admit more air.

Hardy Cyclamens.—These are charming plants for naturalising purposes and growing under trees where the shade is not too dense, and the present is a good time to plant them. All the species and varieties are good, and a little leaf-mould and mortar rubble added to the soil will prove an advantage.

Chrysanthemums.—If the weather proves dry, these surface-rooting plants will need water and, after a thorough soaking has been given, a mulching of short manure will help to keep the roots moist. Stake the shoots when needed, and if black or green fly appears, spray at once with a solution of some reliable insecticide.

Wallflowers should be planted out in lines 1 ft. apart, the centre of the plants being removed when they have made a few inches of growth, and it must be borne in mind that no further pinching is needed. Polyanthuses, Forget-me-nots, Sweet Williams, etc., may be planted out in nursery beds. Water will be needed until the roots are established.

The Hardy Fruit Garden.

Strawberries.—Plants from which the fruit has been gathered should be cleared of runners and dead leaves, and the plantation well hoed. If the plants have carried a heavy crop and, as a result, are in a weakly condition, the bed may be mulched with manure and, if the weather is dry, two or three soakings of weak liquid manure given. A sprinkling of artificial manure would also be of considerable benefit. Where it is intended to destroy a bed, the plants should be dug up directly the fruit is picked and the ground trenched, affording a liberal dressing of manure as the operation proceeds.

Aphids.—Such trees as Plums and Cherries will need watching for green and black fly and, if present, measures should be taken to destroy these pests. Where the trees are producing a crop of fruit which may be approaching the ripening stage, an insecticide ought not to be sprayed over the

harvested. Ventilate rather freely if the weather is favourable, but, in order to economise in artificial heating, reduce ventilation to small dimensions before the sun has gone quite off the house.

The Flower Garden.

Pinks.—Cuttings, or pipings as they are often called, should now be taken and "made," that is, after inserting them firmly in a sandy compost in a cold frame or under hand-lights. Here, it kept close and shaded from the direct rays of the sun they will emit roots in a few weeks, after which they should be gradually inured to full light and air prior to being planted out. I should like to put in a plea for the retention of the beautiful laced varieties, once the florists' pride, but sadly neglected of late. Free use should also be made of such varieties as Mrs. Surland, Her Majesty, Napoleon III and the common Mule Pink. The Allwoodii Pinks are now so widely known that they should require no recommendation here; they are quite a unique class.

Sweet Violets.—Remove all runners as soon as they appear, the object being to build up a single strong crown on each plant, this being essential to the subsequent production of a good crop of large, long-stemmed flowers. Stir the soil from time to time with the hoe, and do not allow the plants to suffer from lack of moisture. Also stir the soil shortly after watering should the latter be required.

Sweet Peas are now flowering, and one need not hesitate to cut freely for the decoration of the home, as the harder they are cut the more profusely will flowers be produced. Uncut spent flowers should be removed before they have time to produce seed. Tie in shoots which fail to catch the stakes, water copiously if drought occurs and feed occasionally. CHARLES COMFORT (Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Ivy-Leaved Pelargoniums are very useful for the conservatory. If good plants are required for next year, cuttings should be rooted towards the end of this month or during August. The young plants should be stopped frequently and grown on steadily in a cool greenhouse. If large specimens are required, three good plants rooted last autumn and now in 48-sized pots should be used to each roim. or 12in. pot. If carefully trained to neat stakes, they should, by the beginning of June next year, be fine large specimens some 6ft. in height and, with suitable care and feeding, will remain in flower for several months. Strong-growing varieties, such as Mme. Crousse, Scarlet Crousse and Souv. de Charles Turner, are best for this purpose. If planted out these Pelargoniums are very useful for covering back walls in sunny greenhouses. They are also excellent as basket plants. Baskets are best made up with young plants, and the latter should be pinched several times to get the baskets well furnished.

Begonias of the tuberous-rooted varieties are now making a good display in the conservatory. The earliest display is obtained from tubers raised from seed last year, and such plants should be assisted with frequent applications of diluted liquid manure and soot water. A quantity of the strongest plants raised from seed sown early this year should be potted up. These plants should be obtained from cold frames where they have been planted out in beds of light rich soil. Such young plants, if well grown make a good succession during late summer and autumn to the earlier batches.

Begonia Evansiana (syn. *B. discolor*) is very useful for the conservatory during late summer and autumn. The plants should now be placed in their flowering pots, which should be 6ins. or 7ins. in size. This plant is one of the oldest of our garden Begonias, being first introduced in 1812. It is nearly hardy, and I know of plants that have stood for several winters at the foot of a warm wall in the neighbourhood of London. It is also interesting as being one of the few Begonias that develop buds in the axils of the upper leaves, such buds attaining a ready means of increase. The beautiful *B. gracilis* also develops buds in the same way. This summer-flowering Begonia is more generally known as *B. Martiana*, which is really a fine variety of *B. gracilis*. This plant must not be confused with the *B. gracilis* of the Continental growers, who wrongly apply this name to a section of *B. semperlorens*. The true *B. gracilis* sends up a single straight and very succulent stem, and enjoys a light rich compost and partial shade during the hottest part of the day.

Bulbs for forcing and pot work generally should be ordered as soon as possible. This is important so that they may be at hand when the proper potting season comes round. Early potting is very essential, as it allows the plants time to develop plenty of roots before they are required for forcing. In the case of Freesias it is very essential that they be potted towards the end of August or beginning of September. In addition to Narcissi, Tulips and Hyacinths which are so largely grown in pots, there are many other bulbous plants that should be more generally cultivated in like manner for the conservatory and greenhouse. The following plants are suitable for this purpose: *Ixias* in many varieties, *Spiraxis*, *Babianas* and *Tritoma crocata*. These are all very cheap and very charming. *Allium neapolitanum* with its pure white flowers is very useful when some five or six bulbs are grown in 48-sized pots. *Ornithogalum arabicum* with its large white flowers with black centres is very fine, although one must confess its regular flowering is somewhat uncertain. *Gladioli* of the ramosus and minus sections are also very beautiful and useful for a supply of cut flower. *Lachenalias*, although charming, are very much neglected at the present day. All the plants mentioned only require the shelter of cold frames in their initial stages, removing them to a cool, airy greenhouse as they come into flower. However, at the proper season I hope to deal with their potting and other cultural requirements.

Royal Botanic Gardens, Kew. J. COUTTS.

ANSWERS TO CORRESPONDENTS

QUESTIONS AND ANSWERS.—All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant.

FLOWER GARDEN.

DIVIDING PRIMULA JAPONICA (L. B.).—Our correspondent does not say in what position the plants are growing. If on a rockery they should be in a moist part, and in any position the soil should be deep, rich and moist, with the drainage ample to prevent stagnant water lodging. Given these conditions and the absence of grubs, which sometimes cause the sudden death of the plants attacked, division may be safely carried out soon after the plants have flowered, in the autumn, or in March.

IRIS MADAME CHEREAU (Folsted).—This is one of the best of the bearded Flag Irises and, if true to name, our correspondent has anything but a worthless specimen. The lavender or sky blue colour in the flowers does vary a little; it is mainly a matter of shade, as a quite open, sunny position where the soil is rich, deep and well drained, is an ideal one for them. This has, of course, been a rather sunless season; in a normal one, probably, the flowers will be quite satisfactory.

ROSE GARDEN.

ROSES AND BLACK SPOT (W. J., Salisbury).—On no account spray with copper sulphate by itself. Bordeaux mixture is the best spray, and it would probably be better to remove the affected leaves as soon as possible. Drastic removal of healthy foliage would, of course, be detrimental.

FRUIT GARDEN.

FIGS DROPPING OFF TREES (W. M.).—The majority of the embryo fruits that form the previous year drop off the following spring or in the early part of the summer when growing in the open air. Of course, a check of any kind, whether from extreme cold or unfavourable root conditions, hastens the fall of these early Figs. Embryo fruits should be forming on many shoots at this season, and the point only of each shoot should be pinched off forthwith; the result will be the rapid swelling of the tiny Figs and their due ripening during September.

MISCELLANEOUS.

NAMES OF PLANTS.—T. W. W.—*Dolichium nudicaule*.—L. H. C., Newick.—1, *Lysimachia punctata*; 2, *Oxalis floribunda*; 3, *Oxalis corniculata* var. *atropurpurea*; 4, *Helianthemum vulgare* var.; 5, *Alyssum maritimum*.—E. F. B., Peebles.—*Saxifraga granulata* var. *dore plena*.—A. R. O. S., Totnes.—1, *Pteris semipinnata* var. *gigantea*; 2, *Polypodium Phymatodes*; 3, *Asplenium Filix-foemina* var. *cristatum*; 4, *Scolopendrium vulgare* var. *furcans*; 5, *Nephrodium Filix-mas* var. *cristatum*; 6, *Polypodium aureum*; 7, *Polypodium Dryopteris*; 8, *Aspidium falcatum*; 9, *Aspidium angulare*.—H. P.—A, *Phyllostachya viridi-glaucescens*; B, *Arundinaria nitida*; C, *Kalmia latifolia*.—Hastings.—*Cratogeomys grandiflorus*.—P. R. T., Herts.—*Phacelia ciliata*.

The Rockets.—If one has a love for a really beautiful and showy old-world flower one should grow the Rocket, *Hesperis matronalis*, which is deliciously scented, especially in the evening, and which remains in bloom over an extended period. This is a hardy perennial, varying in colour from pink and purple to red, reddish purple and white. There are both single and double forms, the double white being grand. All varieties, in addition to their imposing appearance in the borders, are splendid for cutting and reach a height of about a yard. Propagation of the single forms can be effected without the least difficulty by seeds sown in spring, but the most satisfactory way of increasing fine forms is by division. This should be done in July or August by lifting the entire clump and splitting it up into single pieces, which are then at once re-planted either in the reserve garden or their permanent positions. Where one has a stock of established plants, these can safely be transplanted either in spring or autumn. To increase the splendid double sorts, such as the Scotch or French varieties, the easiest method is to strike cuttings. These can be obtained from the parent plants about the middle of June, and should be trimmed clean of the larger leaves at the base and immediately inserted in a bed of light gritty earth in a cold frame. Avoid over-watering, but keep moist at the roots and rather close for a week or two. Light overhead sprinklings are a great assistance in keeping the foliage fresh until roots form. Once roots are formed the frame can be lifted off so as to expose the plants fully to air and sunshine. Early in autumn the plants may be placed in their permanent quarters.

Arsenate of Lead Spraying and Bees.

The issue of the British Bee Journal for July 5 raises the question whether the spraying of fruit trees in blossom with poisonous compounds such as arsenate of lead is dangerous to bees. A correspondent attributes the loss of a great proportion of the workers in some of his stocks to poisoning from newly sprayed Apple trees. He only saved the stocks, he states, by removing the supers and resorting to rapid feeding with syrup. There would seem to be every possibility that bees might be poisoned in the way suggested, and the matter should certainly be cleared up.

An Example Worthy of Emulation.

A member of the Bath City Council has offered to present a large number of fruit trees to be planted in the public parks of Bath. They had, he said in the Royal Victoria Park at Bath some of the most beautiful trees in the West of England. Fruit trees with their blossom in the spring and fruit in the autumn would be beautiful at both seasons. It would be a lesson in self-control for the boys of Bath. They could not tell what the children would do until they tried them and they should not be condemned beforehand. If some of the children were as bad as was suggested, whose fault was it? Could they blame the children? It was grown-ups (men and women) who were responsible for the conduct of the children to-day.

FORTHCOMING EVENTS.

July 17.—Winchester Horticultural Society's Meeting.

July 18.—Hayward's Heath Horticultural Society's Exhibition (two days).

July 19.—Potter's Bar and District Rose Society's Exhibition.

July 20.—Birmingham Horticultural Society's Exhibition (two days).

WATERER'S

IRISES

We grow at Twyford Nurseries (Berks) what is probably the largest stock of Perennial Irises in this country, approximating 300,000 plants in the **BEST STANDARD** and **NEW** varieties, and are able to produce them at lower cost in these large quantities.

The benefit goes to our customers in the greatly reduced prices at which they are quoted, with further special advantages for quantities.

The quality is of the highest standard throughout, and is reflected in the numerous testimonials we receive as well as in the increasing demand.

Our New Iris Catalogue will prove of interest in every garden and help considerably towards reducing the cost of attractive borders. We shall be pleased to send a copy post free on request.

NICOTINE! NICOTINE! NICOTINE!

No Compound, poisonous or non-poisonous, is as effective or as safe as English-made Nicotine for destroying all sucking insects infesting vegetation. It cannot be bought in a more convenient form for spraying or syringing than as—

CAMPBELL'S NICO SOAP (Nicotine Soap). The best Potash Soft Soap plus 7½ per cent. Nicotine. A teaspoonful will make one gallon of strong spray fluid. Prices:—½ lb., 2/-; 1 lb., 4/-; 10 lb., 32/-.

CAMPBELL'S ENGLISH NICOTINE, 95-98 per cent. This is offered to large users or others preferring to make up their own fumigating and spraying compounds. Prices on application.

CAMPBELL'S NICOTINE VAPORISING COMPOUND. Nicotine content, 50 per cent. Prices:—10z., 1/6; 4oz., 3/9; 8oz., 7/6; ½ pint, 9/-; 1 pint, 17/6; ½ gallon, 61/-.

CAMPBELL'S NICOTINE FUMIGATING ROLLS, very simple and effective. In four sizes for 500, 1,000, 2,000 and 3,000 cubic feet. Prices:—7d., 10d., 1/6 and 2/- each.

CAMPBELL'S PATENT SULPHUR VAPORISER. The best method of exterminating Mildew from plants in greenhouses. In two sizes, for 5,000 and 10,000 cubic feet. Prices:—18/- and 20/- each.

Obtainable from Seedsmen, or, in case of difficulty, direct from the Manufacturer—

J. D. CAMPBELL, Nicotine Manufacturer,
5, LUND STREET, CORNBROOK, MANCHESTER.

Avoid disappointment

and make your garden safe against slugs, worms, and all other garden pests by using "SANITAS" POWDER.

It is effective in the extreme, yet economical in use. We will gladly send you a leaflet and sample free, on application. Obtainable everywhere, in Tins, 1/3 and 10d. Special quotations in bulk.

"SANITAS" CO. LTD., LIMEHOUSE, LONDON, E.14

ASK THE MAN WHO USES IT

It's the same with Paint.

THERE'S many a soap that, after a fashion, will cleanse your hands of grit and grease; but most of them jib at paint.

Kit is absolutely in its element with a job like paint or varnish or tar. Just a little water, an easy rub-rub-rub, and in a trice the hands are clean.

Kit is a Speed Soap from the word "Go!" The tin is easy to pack and pull out again, and the special lid lifts off at once. And, if you're in a tearing hurry, you can easily use it without water!

6d PER TIN.

WEBBS' EMPEROR CABBAGE.

(For July and August sowing.)

Undoubtedly the earliest and best Spring Cabbage in cultivation. Immensely popular. Remarkably free from any tendency to "bolt." 6d. and 1/- per packet; 1/9 per ounce.

Mr. J. JOYCE, of Adrahan, writes:—"We tried your Emperor Cabbage in a variety test, 28 in number, obtained from all the best Seed Houses. We have no hesitation in saying that your Emperor was the most satisfactory."

WEBB & SONS, Ltd., The King's Seedsmen, STOURBRIDGE.

WATERER'S GOLD MEDAL RHODODENDRONS and Azaleas, Rare Hardy Shrubs, Alpines in pots, Perennial Irises and Bulbs for Summer planting.—JOHN WATERER SONS AND CRISP, LIMITED, Bagsbot, Surrey; Twyford, Berks; and London.

WAKELEY'S PATENTED HOP MANURE.

The original and only substitute for Stable manure. See advert. on p. vi.

WM. DUNCAN TUCKER & SONS, LTD., Lawrence Road, South Tottenham, N.15.—Conservatories, Winter Gardens, Vinerics, Peach Houses, Portable Buildings, etc.

PRIOR'S NOVELTIES FOR 1923, including

the wonderful new colour Rose Elvira Aramayo and the beautiful new type of Dahlia (Chrysanthemum-flowered) Rosella Amos. Particulars and General Catalogue of Roses, Gladioli, Carnations, Violets, Dahlias, Fruit Trees, etc., free.—D. PRIOR & SON, LTD., Colchester.

RIVERS' FRUIT TREES, ROSES, VINES,

Figs, Oranges and Orchard House trees are of first-class quality, and a large and select stock is always on view. Inspection invited. Price list sent free on application.—THOS. RIVERS & SONS, LIMITED, The Nurseries, Sawbridgeworth, Herts.

GREENHOUSES and Heating Apparatus.—

PARRONS, Horticultural Builder, Oxford Road, Reading.

FREDK. G. WOOD, ASHTEAD, for all

Hardy Plants. Choice Alpines and Border Perennials. Finest Asters, Aubrietias, Chrysanthemums, Delphiniums, etc., finest Oriental Poppies, all 6d. each, 5/- per doz.; finest Border Phlox, 9d. each, 7/6 per doz.; finest Pyrethrums, 9d. each, 7/6 per doz.; finest Chrysanthemums, 6d. each, 5/- per doz. Full descriptive list, 48 pages, on application.—FREDK. G. WOOD, Marsden Nursery, Ashtead, Surrey.

ROCK GARDENS: HOW TO MAKE AND

MAINTAIN THEM. By LEWIS B. MEREDITH. With an Alphabetical List of Plants, with Notes on the Aspect and Soil they require. Third Edition. Fully Illustrated. 10s. 6d. net. (London: Williams and Norgate).

GARDEN NETS.—Best tanned, small mesh,

25 yards by 1 yard, 2/-; 25 by 2, 4/-; 25 by 3, 6/-; 25 by 4, 8/-. Carriage paid. Satisfaction guaranteed. Special Tennis Boundary Nets. Tennis Net from 10/-. Poultry Enclosing Nets. Lists and samples free.—G. JARRETT, Netmaker, Rye.

TENNIS BOUNDARY NETTING.—Lines top

and bottom. 25yds. by 2yds., 20/-; 3yds., 26/-; 4yds., 34/-. Carriage paid. Approval. Nets, poles and all requisites supplied.—E. B. HAWTHORN, LTD., Dept. E, Shrewsbury.

BELL TENTS (Army).—Excellent condition.

New fittings; extra deep walls; all complete, 59/-; New, 115/-. Carriage paid. Approval. New and all kinds of tents supplied.—E. B. HAWTHORN, LTD., Dept. E, Shrewsbury.

DEFY THE BIRDS.—Rotless Tanned Netting,

small mesh, as supplied by us to the Royal Gardens. In two qualities, 50yds. by 1yd., 4/-, 6/9; 2yds., 8/-, 13/6; 3yds., 12/-, 20/3; 4yds., 12/-, 22/-; 25yds. by 8yds., 12/-, 22/-. Odd pieces for bushes, 14lbs., 6/-. Carriage paid. Approval.—E. B. HAWTHORN, LTD., Dept. E, Shrewsbury.

THE WELSH BULB FIELDS, ST. ASAPH.

have been awarded Silver Gilt Medals, R.H.S. and Ghent, 1923. A list of the best Daffodils and Tulips, at reasonable prices, will be sent on application.

COVERING EVERYTHING, MENDING

EVERYTHING and REFASHIONING EVERYTHING, three booklets full of practical hints and useful information by M. STUART MACRAE, and published at 9d. each (postage 1½d.) at the Offices of "COUNTRY LIFE," LTD., 20, Tavistock Street, Covent Garden, W.C.2.

BARR'S SEEDS FOR JULY SOWING.—

HARDY PERENNIALS and ALPINES for the FLOWER and ROCK GARDEN and the most suitable VEGETABLE SEEDS for Summer sowing. Finest Selected Strains and Tested Growth. Special Lists Free.—BARR & SONS, 11, 12, and 13, King Street, Covent Garden, London, W.C.2.

SEWAGE DISPOSAL FOR COUNTRY

HOUSES.—No emptying of cesspools; a perfect fertiliser; no solids; no open filters; perfectly automatic; everything underground. State particulars.—WILLIAM BEATTIE, 8, Lower Grosvenor Place, Westminster.

KING'S ACRE STRAWBERRIES.—New

and interesting List of all the best varieties, with cultural instructions, including all other useful Berries. Pot and open ground Runners now being layered for earliest possible delivery. A useful List sent free on application.—KING'S ACRE NURSERIES, LTD., Hereford.

SPECIAL OFFER.—Herring Nets to cover

all kinds of fruit trees, plants, etc., approximately 80 feet by 30 feet. 10/6 each, carriage paid.—WM. G. GRIGOR, Port Gordon Station, Banffshire.

JAMES GRAY, LTD., Builders of Conservatories, Greenhouses, etc., and Heating Engineers, Danvers

Street, Chelsea, London, S.W.3. Wire: Gray, Kensington 90. Telephone: Kensington 90 & 91.

GARDEN NETTING.—Best small mesh,

tanned, 25yds. by 4yds., 6s.; or 8yds., 12s.; carriage paid. Also Tennis Boundary Netting.—STRAWBERRY NETTING CO., 5, Suffolk Terrace, Lowestoft.

LISSADELL PRIMULAS.—Orange William,

immense orange, 3/- each. Aldean, large crimson purple, Bridget, large orange, Doonfore, large rose, and Rosaleen, large bright red, 12/6 per dozen; 1/3 each. Mixed Hybrids (Asthore x Red Hugh, Beesiana x Red Hugh and Bulleyana x Red Hugh), 35/- per 100, 5/- per dozen, 6d. each; f.o.r. Sligo. Cases extra, at cost. Cash with order.—MANAGER, Lissadell, Sligo.

SUTTON'S CABBAGES.

THE BEST VARIETIES FOR SPRING CUTTING.

SUTTON'S HARBINGER.—The earliest Spring Cabbage in cultivation. Per packet, 1/3 and 1/9.

SUTTON'S APRIL.—Has an unequalled reputation for freedom from tendency to "bolt." Per packet, 1/3 and 1/9.

SUTTON'S FLOWER OF SPRING.—The most reliable Cabbage for the general Spring crop. Per packet, 1/3; ounce, 1/9.

"Your Harbinger and Flower of Spring Cabbages did extremely well this Spring. I had 5,000 heads, which I started to cut on March 24th, and the crop was sold before anyone else had cabbage ready."—MR. P. H. HARTLEY, Moor End.

SUTTON & SONS, THE KING'S SEEDSMEN, READING.

KELWAY'S GAY GAILLARDIAS.—Young

plants now ready. Planted now should flower until September and become well established for early flower next year. The brightest flowers of the garden and most lasting when cut. Write at once for Price List to KELWAY & SON, The Royal Horticulturists, Langport.

DOBBIE & CO., LTD., Royal Seedsmen, EDINBURGH. List of Seeds for present sowing, free on application.

BIRDS' BATHS, GARDEN VASES, SUM-

DIALS, NESTING BOXES. Catalogue (No. 4) free.—MOORTON, 60, Buckingham Palace Road, S.W.

LAXTON'S STRAWBERRIES.—Catalogue

now ready, containing "The Duke," the best early Strawberry yet raised. Also pot plants and open ground runners of all the best new varieties and old favourites can now be booked for early delivery. Catalogues gratis on application.—LAXTON BROTHERS, Bedford.

IRON AND WIRE FENCING for Gardens,

Tree Guards, Gates, Arches, Espaliers, Rose Stakes and Ornamental Garden Iron and Wirework of every description. Send for Illustrated Catalogue. Also Kennel Railing and Poultry Fencing. Ask for separate lists.—BOULTON AND PAUL, LIMITED, Norwich.

GLASSHOUSES.—CARTER & HOWARD, Raynes

Park, S.W.20. 'Phone: Wimbledon 2377.

MIXED DAFFODILS AND NARCISSI for

naturalising, 20/- thousand. Barri Conspicuous, 9/-; Emperor, Empress, Grand Monarque, Soleil d'Or, all 12/-; Scilly White, 15/-; Princes, 6/-; all per hundred. Iris Stylosa, 50/- per hundred. Packing free. Carriage forward, cash with order.—TREWINCE, Portscatho, Cornwall.

WIRE BARGAINS!—Ideal for training peas,

beans, fruit trees, tomatoes, arches, hops, small trees; for green house wiring, clothes lines, tying purposes, fencing, ventilators, etc. Most handy to have in readiness! Waterproof, pliable, steel stranded and long lasting. Drums free. Cash price, 19/6 per mile (full 1,760 yards). Write for free samples and list of bargains to-day!—GOVERNMENT STORES, 315, Seymour Road, Lytham.

COLCHICUMS AND AUTUMN CROCUS for

present planting. List on application.—T. SMITH, Daisy Hill Nursery, Newry.

COLOURED FREESIAS.—List of varieties

now ready.—P. H. DALRYMPLE, Bartley, Southampton.

WANTED, in good condition, "The Garden,"

complete Vols. 1911, 1912, 1917.—H. DALRYMPLE, Bartley, Southampton.

THE GREENHOUSE AND HOW TO MAKE

THE MOST OF IT. A new and practical booklet by the late W. TRELLOVE, 9d. net; by post, 11d. Published at the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

THE GARDEN DOCTOR: Plants in Health

and Disease, by F. J. CHITTENDEN, V.M.B., freely illustrated, 7/6 net, by post 8/-. A prospectus of this practical book will be sent by post on application to The Manager, "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

GREENHOUSE PAINTING AND GLAZING.

—"Vitrolite," superior to White Lead Paint, 18/6 per gallon; cans extra. "Plastioe," the Imperishable Putty, 32/- per cwt.; kegs extra; 7lb. tins, 4/3, post free. 14lb. tins, 5/6 each, carriage extra, tins free.—Full particulars from W. CARSON AND SONS, Grove Works, Battersea.

A Perfect Spray

The most economical and efficient type of hand sprayer for all plants and flowers is the Abol. It gives a strong spray, which may be varied from fine to medium or coarse, as desired.

Abol Patent Syringes embody the finest materials and workmanship. Many of them have been in use for over 20 years.

Full particulars, together with an interesting book on Garden Pests, will be sent to anyone, gratis and post free.

Abol Patent Syringes are specially recommended by the National Rose Society.

Abol

[JULY 21, 1923.]

SUMMER-FLOWERING TREES AND SHRUBS

THE great blaze of colour in the shrubbery comes in spring with the generality of the Brooms, most of the Barberries, the Double Gorse, the Lilacs, the Laburnums and Flowering Cherries and Apples, to mention only a few of the more noteworthy. Some of the Spiræas hang on a little later and the beautiful *Exochordas* usually blossom along with the Scotch Laburnums. After this there is apt to come a blank.

In favoured gardens *Buddleia Colvilei*, illustrated on page 366, is not far behind. This plant in its native state in the Sikkim Himalayas, where it is found at an altitude of 10,000ft. to 12,000ft., is described as a large shrub or small tree, attaining a height of some 30ft. In this country in the South and West it is fairly hardy in the open; in colder parts of the country it is surprising it is not more frequently tried as a wall shrub. Where climatic conditions permit, its successful cultivation presents no difficulty, as it is a strong-growing plant, and, when flowering freely, presents a striking appearance with its flower spikes of small *Pentstemon*-like flowers, which vary in colour from rose purple to a rich dark crimson. There appear to be at least two forms in cultivation; one the lighter-coloured variety which is figured in the *Botanical Magazine*, tab. 7449, and the fine darker-coloured form which has rather smaller flowers. This *Buddleia* is readily propagated by striking the twiggy side growths as soon as they are firm enough to prevent damping, such shoots rooting readily under a bell-glass in a cool house. Success is, however, more certain if a pot-grown plant is introduced to a greenhouse and the young growth secured for cuttings.

Then comes quite a number of the Mock Oranges, perhaps the very best being the

species *Philadelphus grandiflorus*, which has the merit—as most of us think—of being scentless. *P. inodorus* is an allied species, though less elegant in flower and foliage. Some of the dwarf-growing *Lemoinei* hybrids are late to flower, notably *P. purpureo-maculatus*. Another very handsome (probably hybrid) Mock Orange is *P. insignis*, sometimes—especially in Continental lists—catalogued as "*Souvenir de Billiard*." This, like *P. grandiflorus*, to which it probably owes relationship, grows 10ft., 12ft. or 14ft. high. The flowers, produced as freely as on the small *Lemoinei* forms, are cupped and pleasingly, but not strongly, perfumed.

About this season *Romneya Coulteri* first begins to expand its satiny, golden-stained platters, while a great wealth of *Escallonias* helps greatly to keep the shrubbery bright. The great stand-bys in this family are still *E. E. macrantha*, *Philippiana* and the hybrid between them, *langleyensis*. There are quite a number of new forms with *Philippiana* and *macrantha* blood—*edineensis*, *newryensis* and *Donard Seedling*, for instance—and these are useful additions

to the shrubbery, but if we were confined to two *Escallonias*, the sorts selected would still be *macrantha* and *langleyensis*, and probably if three were wanted *Philippiana*, deciduous though it be, would be the third.

Escallonia rubra, somewhat in the way of *macrantha* as far as general appearance goes, is a taller grower, ultimately attaining a height of 15ft. or so. It is fairly hardy in most localities, but less handsome in flower than *E. macrantha*; nor does it, like that species, flower the year round. The only other kind useful for the general run of inland gardens is *E. exoniensis*, a hybrid of *rubra* parentage sent out by Messrs. R. Veitch of Exeter. This easily attains a height of 15ft. and the flowers are white or bluish white. This, like *E. macrantha*, is a continuous bloomer and, given open weather, it is quite possible to pick sprays in midwinter.

The *Ceanothuses* of the *americana* and *azureus* clan, including the invaluable *Gloire de Versailles*, provide cloudy blue colouring at this season and, like the *Escallonias*, they will see that the shrubbery is not devoid of blossom until late in autumn.

Another beautiful shrub with the same estimable trait is the scarlet and yellow *Desfontainea spinosa*, which, alas! stands our winter outdoors only in favoured gardens. There is quite a batch of late-flowering Brooms of which the blossoms last into July, but there is matter here for a separate article. The Spanish or Rush Broom, *Spartium junceum*, is really in a class apart, not only because it has a genus to itself, but on account of its really late-flowering and very distinctive characters. This is the only Broom which is at all useful for cut flower. The golden, sweet pea-like blossoms never wilt when placed in water. The *Spartium* is apt to prove none too

AMONG THE HANDSOMEST OF DAISY BUSHES, *OLEARIA MACRODONTA*.

give shelter and to attract the bees.

Most people keep too little for the health garden. Suffice it here to say that a large number of these flower in late summer. Similar conditions rule out the Roses, though several species and the great majority of hybrid Ramblers flower in July. It is only necessary here to mention them so that they may not be overlooked when planning the shrubbery.

There are two of the Magnolias which produce blossom in late summer and autumn, though neither can be said to make a show of flower at any one time. *M. grandiflora* is evergreen, and in most districts appreciates the shelter of a house wall. The other species—the Swamp Bay, *M. glauca*, so called from the bright glaucous colouring of the undersides of the leaves—is deciduous or sub-evergreen. Both species are somewhat variable, and there are named sorts in commerce.

The Hydrangeas are all summer and autumn flowering shrubs. The kinds usually met with in shrubberies are paniculata, including its sterile variety *grandiflora*, and *arborescens*, which produces masses of greenish or yellowish white trusses. A new sterile form of this *H. a.* *grandiflora* has pure white flowers, but, as in the typical plant, the trusses have a tendency to "go over" at the neck, especially after rain. Many a beautiful lady has been spoiled by bad ankles, and the weakness of the footstalk is certainly a serious detriment to this Hydrangea. *Hydrangea Bretschneideri*, which is earlier to flower than most, reminds one irresistibly of the wild Guelder Rose, *Viburnum Opulus*, when in blossom. It is quite

large, but it is said that its flower-freckles should have a more artistic effect.

Hydrangea hortensis is hardly enough anywhere near our seashores, and may be seen outdoors in many a cottage garden in mid-Sussex, to go no further afield, but is unreliable at Kew. Where the type plant stands outdoors the splendid variety *Mariesii* should be grown. The marginal flowers of this variety only are sterile and of pleasing mauve-pink colouring. Comparatively few in number, they are rendered conspicuous by their size, being often six inches across. There are, however, at least three forms of *Hydrangea hortensis*—or, at any rate, very closely related species—which will stand outdoors in many of the more favoured inland counties. These are called *acromata*, *Lindleyi* (or *japonica*) and *stellata*, the two former with sterile flowers only at the corymb flower, and the last named with curious "double" flowers.

The great glory of the late summer and early autumn shrubbery, however, is *Buddleia variabilis*. This was not always a highly esteemed shrub, and for its neglect there are two explanations. In the first place, the forms originally introduced from China were really not comparable to those collected a few years later mainly by Mr. E. H. Wilson; secondly, the necessity for hard pruning, if really fine trusses are desired, was probably not, at first, so well understood. The best forms in cultivation are in their order of coming into flower: *Veitchiana*, *magnifica* and *superba*. There is usually a week or ten days between *Veitchiana* and *magnifica*, and a good fortnight between the latter and *superba*. *Veitchiana* and *superba* are of much the same lilac and orange colouring, though the latter makes a finer spike. *Magnifica*, however, has flowers of richer colouring,

a deep but bright violet purple, contrasting well with the orange at the throat.

No reference to summer-flowering shrubs would be complete which overlooked the Olearias. The species illustrated on page 365 (*O. macrodonta*) is not only quite the handsomest, but one of the earliest to flower. It stands outdoors—away from a wall—in some of the Midland Counties, and is much harder than is generally supposed. The same may be said of *O. stellata* and the very similar but but rather laxer and larger-flowered *O. Gunniana*. The tenderness of the "Daisy-bush" family is largely legendary. Some of those considered most tender are at the present time harder than many *Cistuses* which are habitually grown outdoors, though the beautiful *O. semi-dentata* will not, at the time of writing, stand outdoors except in specially favoured districts. The fact is that it is unwise to accept evidence of a newly introduced plant's tenderness as final. Many species at first proved tender have in the long run acclimatised themselves, and this is particularly so with the Olearias. A light well drained soil and a sunny aspect should, of course, always be afforded the choicer ones. *Olearia nitida*, the curious semi-succulent *O. nummularifolia* and the truly remarkable *O. insignis*, which in its younger stages looks herbaceous, all stand outdoors in such inland counties as Warwickshire.

There are other families of plants which yield flower at this season, but, except the Veronicas—the most useful of these is *salicifolia*—and the Clematises, which are climbing shrubs, we have mentioned the showiest and most important, though mention should certainly be made of *Caryopteris* and *Indigofera*.

THE SWAMP BAY, *MAGNOLIA GLAUCA*.
The foliage is vividly glaucous beneath.

THE ROSE-FLOWERED *BUDDLEIA COLVILLEI*.
Needs the shelter of a wall in most districts.

NOTES ON FREESIAS

COMPARED with Hyacinths, Tulips and Bunch-flowered Daffodils, the Freesia is a new-comer into the world of decorative greenhouse flowers. One of the best books on bulb culture that I have come across is "Bulbs and Bulb Culture," by the late Mr. D. T. Fish. The edition which I possess was probably the last; at all events, it was published in 1885. The Freesia is not mentioned—not even *refracta* or *refracta alba* nor *Leichtlini*. The coloured Freesia did not appear for a long time after this. *Armstrongii*, which is the parent of all the coloured varieties, was only found in 1898, and the first bulb was not flowered in England until the following year. Hybridists, however, at once seized upon it, and the ball of new varieties was set rolling. Lavenders, roses, pinks, heliotropes, warm apricots, and other shades and colours have now come into being along with fine new whites and yellows of all kinds from pale primrose to deep orange. These last probably owe but little to *Armstrongii*, unless the new-comer has in some way stimulated a dormant factor for yellow into life.

Raising seedling Freesias is very fascinating if only a sufficiency of greenhouse room can be given up to the young plants. These will bloom in February and March if a low temperature of 45° to 50° is not exceeded in the winter months and enough warmth kept up at nights to exclude frost. Seed should be sown *very thinly* in August or September and kept under glass. After germination the seedlings should be grown on and given much the same treatment as the bulbs. Then when the foliage has died down the young plants should be very carefully turned out so as to keep each bulb with its offsets together. In August every little lot is put into a 3½ in. pot and grown in the usual way. As far as my experience goes no one has got to Tipperary yet. It is still "a long, long way to go." I am very fond of Tulips, I am very fond of Daffodils "that come before the swallow dares." But I want something before Daffodils "dare." I have found my philosopher's stone in the Freesia. To those who feel the call of Nature to give her offspring that

chance in life which is beyond her powers. To be able to do this and to be a fellow worker with but after, the Grand Dame!

"Her 'prentice han' she tried out man,
And then she made the lasses, O!"

"Yes," someone is thinking, "why all this ecstasy over Freesias? Are there no other flowers in

A MEDLEY OF COLOURED FREESIAS.

the world?" Freesias have "found" me, as Crocuses, and Orchids, and Pansies, and Daffodils, and Delphiniums, and Roses, and Carnations and Auriculas—to draw one's bow at a venture—have found others.

Two problems perplex the grower of coloured Freesias—duds and breaking. I do not think my friend Mr. Dalrymple used to take all I have written at various times about Freesias breaking quite seriously. I fear he has had a rude awakening this last blooming season. "'Et tu, Brute!' You, Wistaria!* you!" They seem to manage matters better in Holland. Mr. John Hoog

*Wistaria was raised by Mr. Dalrymple. It was the apple of his eye. "My W. is perfectly lovely, I wouldn't give an offset of it for all the Apotheose in the country."

has recently written to say that this aggravating behaviour is unknown among his many varieties at Harlem! A small boy at a preparatory school came in late for dinner. The master noticed he said a remarkably short grace to himself. Curiosity prompted him to ask him what he said. "Marvellous," he replied. That's the word I apply to Mr. Hoog's experience. I wish he would tell us how it is done. I have grown a large number of the Zwamenburg varieties, and (yellows excepted) only Dainty and Conquest have remained unchanged. Duds are more understandable. They occur when bulbs are not sufficiently ripened. I have called them "Weary Willies," but I "apd." The fault is in the cultivator, who has failed to give them the necessary warmth before potting them. I advise everyone to try keeping the bulbs for a fortnight, or three weeks if possible, in a warm temperature of 65° to 70° before planting. Last autumn I tried it for the first time and the result surprised me. Several friends have written to say they have suffered from duds this year. May I advise as a safeguard for another season this treatment? One compensation about duds is that one seldom finds a bad one. This is a comfort when the variety is a valuable one, for they will behave all right another year and need not be thrown away.

FREESIAS AS WINDOW PLANTS.

Being the possessor of Bailey's big American Cyclopaedia, I have read all that is written under the head of Freesias. It surprised me not a little to find these words: "they flourish in home windows with less care than most other bulbs." I would never have thought it, and my house windows being quite out of the question for allowing me to make a first-hand experiment, I have never done so. However, a present of a few bulbs to the late Mr. John Bain when he was living in retirement at Gairloch in Ross-shire has shewn me there was far more truth in the remark than I imagined. This famous gardener wrote in 1920: "I had a most lovely potful of Merry Widow Freesias. Every bulb flowered." Along with Hyacinths and other bulbs they made "quite a show in my cottage window, especially the Freesias." We are not all of us John Bains, but as the proof of the pudding is in the eating, I asked him if he would give me some details of how he did it so that I could pass on the information to others who want to try window culture. The letter from which I quote is dated November 2: "After I potted them in the autumn, I left them out of doors until they started well into growth, and took them in when there was any sign of frost. Being so close to the sea we do not get any sharp frost until late in the year, so I have one or two pots still out of doors and only took the most advanced in at the end of last week. My windows face north-west, so get but very little sun through the winter. I gave the pot of Merry Widow that flowered so well last spring when it began to show flower a little potato guano, which I think it liked very much. It gave the foliage a nice dark colour and the blooms were very fine." I wish we had been told something of what happened after November. I can only suppose the usual routine was followed: turning the pots round daily, careful staking and watering, putting them out of reach of frost at nights, giving all the sun and air possible and so on. Perhaps some kind reader who has successfully negotiated Freesia culture in a window will put pen to paper and tell us how he does the trick. The writer in Bailey seems to say that only the Chinese Narcissus is easier to manage. What a popular plant the Freesia, with its delightful and unmatched aroma, might become if only the general experience of growers confirms its adaptability for window gardening.

JOSEPH JACOB.

THE SUN-LOVING ÆTHIONEMAS

THE genus *Æthionema* consists of about forty species of somewhat low growing plants, native chiefly of the Orient, although six or seven are found in parts of Southern Europe. Many of them are of great beauty, very free flowering, and well suited for dry, sunny positions in the rock garden. Although perennial in habit, with shrubby stems, several kinds are short lived and require to be propagated frequently in order to keep up the supply. An exception to this is *Æ. amicum* as well as *Æ. ibericum*, both of which, when planted in suitable situations, continue to flower annually for several years, the former making

a beautiful display on a sunny ledge. Quite a dozen species have been, or are, in cultivation, the best of which are:

Æ. AMICUM. This is an Armenian plant similar in habit but more profuse in growth than the better known *Æ. pulchellum*. It has rather longer and greener foliage, with racemes of larger pale pink flowers. Commencing in April, its racemes of flowers are produced throughout May and June, making it a valuable plant for the sunny rock garden.

Æ. ARMENIUM. A choice little species, also from Armenia, with narrow, closely set foliage on stems only 3 ins. high. The deep pink flowers

are produced in short racemes in early spring. It is principally a plant for growing in pots for the alpine house. A form or hybrid of this is *Worley Rose*, a very free-growing, hardy kind with rosy pink flowers.

Æ. CARYOPHYLLUM is an annual from the Orient, making little tufts 2 ins. high, with fleshy oval leaves and pale pink flowers in summer. It may be sown in the open ground in spring.

Æ. CORDATUM.—Although distinct, this species has not much to recommend it. It has, unfortunately, a lax, untidy habit. It comes from Asia Minor and Syria, and has fleshy cordate leaves and yellowish flowers in June.

Æ. CORNIFOLIUM (syn. *Iberis jucunda*).—The native home of this little gem, which also goes by the name of Lebanon Candytuft, is in the mountain ranges of Asia Minor and Syria. It is not quite hardy in the northern parts of this country, but in the warmer south it can be grown with success as a crevice plant or on a rocky ledge. It forms a pretty little bush about 4 ins. high and rather more in diameter. Very slow-growing, it should only be associated with the choicer and neater-growing rock plants. It does best in loamy soil with plenty of limestone chippings mixed with it. Perfect drainage is essential, as, indeed, it is with all the other species. The delicate pink flowers are produced in July and August in densely crowded, almost umbellate racemes, and are veined with a deeper rose. The glaucous evergreen leaves are somewhat cuneate in shape and about half an inch long.

Æ. GRECUM is a tufted little perennial 6 ins. high with oval, fleshy leaves and pale pink flowers in racemes. It comes from Greece.

Æ. GRANDIFLORUM.—This is a shrubby perennial from Northern Persia which grows to a height of 1 ft. to 18 ins., with numerous twiggy stems clothed with linear, nearly green leaves. During the summer months it gives a profusion of deep rosy pink flowers in very long racemes. It is not so hardy as some of the others and requires a warm, sheltered position, preferably planted between stones where it is assured of ample drainage. When once established it resents disturbance and many plants are lost through attempted removal. Seeds are produced sparingly, but it may be increased by means of cuttings.

Æ. IBERICUM is probably the hardiest member of the genus, forming a tuft of low-lying foliage covered in April and May with short racemes of white flowers. It does well in the rock garden in good loamy soil, and may be increased by division. It is found on the Taurus range of mountains in Cilicia.

Æ. PULCHELLUM (syns. *diastrophis* and *persicum* of gardens).—This charming plant forms a bush up to 8 ins. high, with numerous twiggy stems clothed with linear glaucous leaves. During the spring and early summer months the pale rosy lilac flowers are produced in dense racemes, quite covering the whole plant. It is one of the best, quite hardy on a well drained ledge, and prefers a loamy soil with plenty of limestone chips.

Æ. THOMASIANUM is a pretty little alpine from the Piedmont with rosy lilac flowers and suitable for the moraine.

Except in the case of the annual kinds, seeds are not produced very freely, but all the perennial species may be increased by means of cuttings in the summer as soon as the flowering season is over and the plants commence to produce fresh shoots. The cuttings should be inserted in pots in a very sandy soil and kept in a close frame till they are rooted. They may then be potted off singly in small pots so that the pots get full of roots before the winter. The best time for planting out is in the late spring. W. J.

THE PALE, ROSY LILAC ÆTHIONEMA PULCHELLUM.

ÆTHIONEMA AMICUM HAS GREENER FOLIAGE AND LARGER FLOWERS THAN Æ. PULCHELLUM.

MODERN ROSE CULTURE

IF the last twenty years has witnessed a greater revolution in Rose culture than was achieved in all previous time since Theophrastus wrote his celebrated book on the subject in 287 B.C., few would dare to assert that the Roses of to-day are in any sense superior to those of Dean Hole's time. Varieties have, of course, increased to an extent undreamed of even a few years ago. English and Irish hybridists, stimulated into activity by the skill and competition of the French rosarians, still among the keenest in the world, have flooded our gardens and shows with Hybrid Teas. Germany, Holland and even America have done their part in this race for priority until the average rose-grower has become utterly incapable of keeping pace with each recurring season's output of novelties.

The primary reason why it is impossible to make comparisons between the Roses of one generation and another is that Rose culture has never been carried on with any definite objective in view. There has been no great or common ideal of any stability, so that the blossom which was lauded yesterday might well, to-morrow, be neglected for the more novel attractions of some newcomer. Then any conception of what should constitute the perfect Rose has probably never existed, for fashions and tastes change in this as in other things. Even our gardens themselves have lately undergone a period of reformation, during which earlier designs have been supplanted by entirely new ideas, so that the formalities of the later Victorian days have become as remote as those of Tudor times.

However, if the amazing multiplication of new sorts of Roses has been the means of producing some notable and enduring results, annually revitalising one of the most important branches of gardening science, it has at the same time been instrumental in bringing about a reversion towards Roses of an earlier type. This, I think, is the most pronounced feature of modern Rose culture. We, doubtless, grow as many Roses of the bedding or decorative classes as ever we did, though the orthodox rose garden does not appear to be the essential adjunct that once it was deemed to be. But the tendency nowadays is to recall and reinstate those rare old Roses of an earlier England, the old and half-forgotten favourites, like the Moss Rose, the Damask and the Cabbage, whose exquisite fragrance—surely the Rose's most precious possession—may be sought for in vain in "the scentless breath" of too many modern creations.

This awakening of a fresh interest in these ancestral types has, however, extended further than I have indicated. From those groups of

THE ROSE-COLOURED ROSE BESSIE CHAPLIN.
This secured a Gold Medal at the Great Summer Show.

Tudor and other varieties which rose historians have lately established in Shakespeare's garden at Stratford we have gone right back to the Briar or single forms, even to the Roses of Horace, who described the ephemeral character of their blossoms and their fragile loveliness with the one word, "short-lived." Not only have our own Dog Roses and Sweet Briar been brought into our gardens, with or without the splendid adornments wrought upon them by the cunning of the hybridist, but the ends of the earth have contributed their share. From China in particular have some wonderful species been introduced. Indeed, the citron yellow *Rosa Hugonis* and the beautiful *Rosa Moyesii*—unapproached among singles in the texture of its velvety petals, and without a rival in the quality and depth of the crimson-searlet which frames its circle of gold—may be mentioned as a brace of singles destined to exceed in public esteem any modern Rose of garden origin. Again, in some of the Briars introduced by Lord Penzance, and which still bear his name, no less than in many other productions, notably of the Irish nurseries, one is attracted not only by that elegant simplicity which is so appealing a feature of the single form, but by the true rose perfume and those rare blends of colour which so often betray the "blood" of certain species of

the East and which might be described as tones of glowing orange chrome.

But single Roses have qualifications other than these. Many of them are species, and for the species, as distinguished from the mere variety or hybrid, many gardeners of to-day have a decided predilection which is in part no doubt due to the enormous extension in the culture of alpine plants during late years. There is, indeed, a peculiar interest attached to a plant of specific rank which will always afford it a distinction seldom accorded the "made-up" article. Then it will not be overlooked that the majority of the Roses of this type are June Roses. That in itself would be sufficient to make a strong appeal to our national sentiment, for the great bulk of the Teas and Perpetuals, no less than those of the ubiquitous Rambler class, do not usually come into full bloom until July is well in. Thus have we, in making this return to our first loves, not only indicated in a very practical sense a phase of that modern trend which is ever leading us towards the attainment of a clearer vision and deeper appreciation of natural beauty in gardening, but we have achieved the possibility of realising that June in the garden may be, what it has always been in the lane, an actual rather than traditional "Month of Roses."

A. T. JOHNSON.

FERNS FOR THE WATERSIDE

THE common idea that Ferns imperatively demand very large supplies of water, though true in the main, is by no means universally so. Nature is for ever searching for homes for her children, for unoccupied territory to plant with growing things. Thus it has come about that walls, which one would imagine to be quite incapable of supporting them, are found literally covered by Spleenworts, Polypodiums, Hartstongues, etc.; while, again, in damp, swampy places one finds glorious masses of Marsh Shield Fern, Sensitive Fern, Royal Fern, Cinnamon Fern, Chain Fern, etc. Obviously, then, when considering our plantings, it is the old, old problem—that of fitting the plant to the place. Nature will always back one's efforts, but one cannot reverse her decisions. There are Ferns that *do* imperatively demand moisture, and, if one has a bit of streamside or water garden with a "squishy" slope on the margin, one possesses an ideal opportunity for grouping that will appear attractive right through the year. A Fern is always an attractive plant even at its deadiest and dullest, with its sere brown fronds so cosily tucked over the crown, like a blanket protecting from cold and frost. See these, too, when covered with hoar frost and one has a picture nearly as fascinating as the uncoiling of the fresh green fronds in late spring, when these seem as if they were running a race with time and *must* complete a certain amount of extension before sunset.

When selecting a site for waterside planting a vital point is to mark the lowest summer level of real moisture and see that planting is not done above this. Mere proximity of water is not enough: it must be available for the roots to drink, or the fronds become a helpless, flaccid mass upon the ground, a condition of things which, if prolonged, results in death. It does not matter if the water occasionally overflows and floods the roots; they will tolerate this for short periods, but they must not be left high and dry.

Onoclea sensibilis is very free growing in a really wet site, extending itself by means of creeping

mazones, from which spring the distinctive fronds to a height of from 1ft. to 2ft. Owing to the thin texture of the fronds this Fern does not love sunlight and is happiest when a good bed of rich loam is put down for it in partial shade. The Marsh Shield Fern (*Nephrrodium Thelypteris*) is very hardy and one of the most delightful when a low-growing species is required for planting by the waterside. In making up the soil for this, old potting compost or fibrous loam is excellent, while it especially appreciates being really near water and having plenty of pieces of rock among its roots.

Whenever I see a good specimen of the Royal Fern, *Osmunda regalis*, I always feel a sensation of envy. I should, even were I the possessor of a dozen of the best, so unique and handsome are

the magnificent fronds and wide spreading, as they tower upwards to a height of 4ft. or more, and, during the first half of the summer, shew the rapid growth of the curious fertile fronds which have gained for it the name of "flowering" Fern. Another *Osmunda* that thrives gloriously is the Cinnamon Fern, *O. cinnamomea*, of which the young fronds and stems are covered with cinnamon-coloured wool. The elegant pale green fronds form a bold and handsome tuft that never looks better than where isolated from taller plants and set in a carpet of some low-growing plant that runs right close up to the roots. One of the most beautiful garden pictures that I can call to mind consisted of a giant specimen of this Fern surrounded by dozens of *Primula japonica* in deep crimson red.

The Hart-tongues grow almost out of recognition by the waterside, the thick, leathery leaves attaining a length of 3ft. and even 4ft. where there is sufficient moisture. The wonderful crispum varieties are no less successful than the commoner forms, and a lavish use of these alone is sufficient to create an unrivalled picture of beautiful fern. The Chain Fern, *Woodwardia angustifolia*, is quite dwarf compared with the tall growers which we have been considering, and therefore makes a grand carpeter for lavish planting between taller and more vigorous growers. The fronds attain a height of about 1ft. and a width of 3ins. to 4ins. The Virginian Chain Fern, in addition to moisture, must have space, for it will quickly cover a yard of ground with its long and narrow and simply divided fronds. HAVELOCK.

HARDY PLANTS AT WESTMINSTER

THE fortnightly meeting of the Royal Horticultural Society on July 10 marked the reversion to single-day shows for the remainder of the season. There was, however, no noticeable falling off in the quality of the exhibits. It was essentially a hardy plant show. Delphiniums, in particular, were extremely well shewn by, among others, Mr. H. J. Jones, Messrs. Blackmore and Langdon, Messrs. Kelway and Son, Messrs. R. H. Bath, Limited, and Mr. T. Carlile. Mr. Jones' exhibit followed the style he has made memorable with displays of Chrysanthemums, Dahlias and Phloxes. Tall, bold pilasters formed a background to a multitude of big vases in the foreground. Pinkish mauve and soft helio shades predominated, and we especially noted Andrew Carnegie, Roselaire, Elaine Lettor, Manny Heel and Ryecroft, all in this restricted range of colouring. Relief was afforded by the stronger colouring of F. W. Smith, The Alake, etc. Particularly noticeable was the high quality of the individual spikes. (Gold medal.)

Messrs. Blackmore and Langdon had huge masses of such splendid sorts as Millicent Blackmore, the rosy purple Lord Rosebery, The Alake and the brilliant Blue Boy. In Messrs. Kelway's large collection we noticed James William Kelway, which might be described as a glorified The Alake, and Star of Langport, a beautiful pale-coloured variety. This firm also had a number of vases of their named Gaillardias. Messrs. Bath's most notable varieties were, perhaps, Mrs. Creighton and The Alake, but they had a very good and complete collection. Mr. Carlile also had a nice lot, in which strong-coloured sorts predominated, so that his exhibit and that of Mr. Jones, one on either side of the entrance to the tea annexe, provided a foil to one another. The "Reckitt's blue" F. W. Smith was very conspicuous on this exhibit.

Messrs. Barr and Sons had an interesting mixed group of herbaceous and bulbous plants, including *Campanula persicifolia* Telham Beauty, Madonna Lilies, the tall Catmint,

Nepeta Ukrania, and *Salvia virgata nemorosa*, which makes so splendid a foil to flowers of soft yellow or buff colouring. The Irises included *Mon-aurea* and *ochroleuca* Queen Victoria, the latter a fine form with bold falls and some excellent forms of the English Iris, *I. xiphioides*. The deep almost true blue Nimrod was noteworthy among these.

Messrs. Carter and Co. filled quite a length of tabling with Iceland Poppies in deep rich orange yellow and pure white, as well as a range of

delicate salmon and apricot tones reminiscent of the cultivated Alpine Poppies.

Messrs. George Bunyard had some very interesting herbaceous plants, but this exhibit of the Maidstone firm suffered from overcrowding. Presumably, space had not panned out as expected. The most striking things here were *Eremuri*—Shelford and Bungei; *Iris* Shelford Giant, which might be described as a handsome but pallid *ochroleuca*; and Japanese (*Kämpferi*) Irises.

Messrs. Rich and Co. shewed their Oxe-eye Daisy *Rentpayer* and a much better one with flowers like those of a good white *Pyrethrum*—*Chrysanthemum leucanthemum* Beauty of Bath. Messrs. Carter Page and Co. shewed Sweet Williams well, especially the black crimson Negress. Cup-and-Saucer Canterbury Bells and herbaceous plants generally were also shewn, among the last named the deep lavender *Catanache cœrulea*, so effective for cut flower.

Messrs. Tucker and Sons brought from Headington, near Oxford, an interesting collection of alpine plants and herbaceous cut flowers, mostly the former. *Edraianthus dalmaticus*, *Pentstemon heterophyllus*, *Allium pedemontanum*, the quaint and woolly-foliated *Origanum Dictamnus* and the rare old dwarf Sweet William, *Dianthus barbatus magnificus*—once a favourite in the markets—were, with a great variety of dwarf Campanulas, some of the most interesting plants on view. Among the cut flowers were *Lilium regale* and the rather effective purplish rose *Centaurea rigidiflora*.

Messrs. Joseph Cheal and Sons had a bank of cut hardy flowers, including such useful perennials as *Sidalcea Listeri* and a really good deep-coloured form of *Campanula lactiflora*. Among growing plants also shewn we noted the turquoise *Pentstemon heterophyllus*, the golden platters of *Asteriscus maritimus* and such useful Campanulas as *W. H. Paine* (one of the garganica kindred) and *Raddeana*.

Messrs. Maurice Prichard and Sons exhibited alpines in pots, including quite a collection of dwarf Campanulas, these including *kewensis*,

THE SOFT LAVENDER PEACH-LEAVED CAMPANULA, *C. PERSICIFOLIA* RYBURGH BELLS.

SOFT LILAC, ROSE SHADED DELPHINIUM
MY LADY.

Miss Willmott, *Miranda* (like a bloated form of the last), *pulsilla alba*, W. H. Paine, G. F. Wilson and *pulloides*. One of the prettiest of the *Scutellarias* was noted here—*S. indica japonica* it was labelled—and the always attractive *Sedum coruleum*.

Right opposite to the entrance to the hall Messrs. Sutton and Sons had a circular bed of Cup-and-Saucer Canterbury Bells in purple, mauve, white and rose pink. These were well grown plants which had reached perfection we should say about a week before the meeting. Some of the blossom was distinctly *passé*; still, they made a brave show.

A second exhibit of Messrs. M. Prichard and Son consisted of herbaceous stuff, much of it suitable for waterside planting. The *Astilbes* included *Vesta*, *Venus* and *Peach Blossom* and *Spiraea Aruncus* was also included. A fairly wide selection of *Kämpferi* Irises, *Veronica spicata* and variety *rosea*, and *Delphinium Maurice* Prichard were other interesting items. The last named is, apparently, a *D. nudicaule* hybrid with bluish pink blossoms. The Christchurch

firm also had a goodly selection of Pinks on view. Of these we selected the rosy *Summer Charm* is especially effective.

Mr. Frederick G. Wood of Ashted, Surrey, had an interesting collection of herbaceous flowers, including a good form of *Campanula lactiflora* and a form new to us of the native *Verbascum Blattaria* (V. B. *grandiflorum*) with shapely buff pink flowers. This should be excellent for naturalising in the woodland wild. *Anchusas*, *Sidalceas*, *Prunella grandiflora* and dwarf *Campanulas* were also well shewn here. A fine pan of *Campanula Hostii*, in particular, found many admirers.

Mr. G. W. Miller's exhibit was noteworthy for the lovely *Campanula persicifolia* Dainty, a shapely semi-double form with flowers of the palest lavender tinting, giving a delightful chintz-like effect. *Lilium pardalinum* and *L. Martagon punctatum* were also attractive.

Messrs. J. Waterer, Sons and Crisp had, as usual, some interesting plants on view. The quaint little magenta-flowered *Verbena Maconette* with its irresponsible white stripes, *Wahlenbergia vincaeflora*, *Sisyrinchium consolida*, *Potentilla Tonguei* (buff, orange eyed), the bright rose *Erodium cicutarium* and *Campanula Raddeana* being a few selected almost at random.

Messrs. Lowe and Gibson of Crawley Down, Sussex, had a small collection of *Herbertii* Pinks in front of a number of vases of seedling *Gladioli*. The best of the Pinks were *Queen Mary*, *Simplicity*, *Model* and *Victory*. The *Gladioli* were stated to be all from seedlings raised from seeds sown in 1922. They were mostly *primulinus* forms of varied and pleasing colouring and excellent form.

The most conspicuous plant in Mr. B. Ladham's exhibit was *Lavatera Olbia*, but more interesting, perhaps, were the blue and white *coronata* forms of *Campanula persicifolia*, which correspond to the Cup-and-Saucer Canterbury Bells inasmuch as the sepals are petaloid. The effect produced is, however, very different, and the flowers have rather a hose-in-hose effect.

On Mr. George Downer's exhibit we noted, besides his strain of "red" *Lupins*, *Romneya trichocalyx* and the quaint and aptly named

Gaillardia Ruffle of which the much crimped blossoms are golden orange with a dusky eye.

Mr. G. Reuther had, as usual, something of everything, especially of everything uncommon. The Swamp Honeysuckle (*Rhododendron viscosum*), *Carpentaria californica*, a number of useful *Escallonias*, some *Philadelphuses* (notably *Virginal* and *purpurea maculatus*), *Desfontainea spinosa*, *Orchis foliosa*, *Cypripedium calceolus*, *Ixias* in many forms (including *viridiflora*), the quaint little *Lilium Grayii*, *Campanula Raddeana* and *Pentstemon Cobaea* were some of the more noteworthy.

Mr. Ernest Dixon of West Hill Nursery, Putney, made quite a display with the dwarf white *Campanula Spethley*, which attracted so much attention at Holland House in 1921.

Messrs. G. Stark and Son of Great Ryburgh had an exhibit of *Campanula persicifolia* Ryburgh Bells (see under "New and Rare Plants") and their Ryburgh strain of *Papaver Rhoeas*, all more or less double and wonderfully beautiful in their range of salmon, peach and apricot.

Mr. Charles Turner of Slough had branches of interesting flowering shrubs, including *Ochna multiflora* with vermilion bracts and green and black fruits. This will not stand outdoors in many districts, but is an excellent plant for the cool greenhouse. The scentless *Philadelphus grandiflorus* and PP. *Gordonianus* and *Pavillon Blanc* were also well shewn.

Mr. W. Wells, jun., of Merstham had a very useful collection of herbaceous plants in the orchid annex. *Salvia virgata nemorosa* (true) was exceedingly attractive as associated with *Hemerocallis Thunbergii*, *Erigerons*, *Delphiniums*, *Sidalceas* were all well displayed, so was a bold mass of *Alstromeria aurantiaca*.

Mr. E. Scaplehorn of Beckenham had *Gladiolus Halley*, English Irises, *Ixias*, *Scabiosa caucasica* and other herbaceous plants.

Carnations, as usual, were numerous. Mr. Englemann shewed a fine collection of *Perpetual*-flowering varieties, among which the following were conspicuous: *Saffron*, a self-descriptive flower; *Topsy*, deep crimson; *Thor*, orange scarlet; *Laddie*, salmon pink; and *Peerless*,

THE GOLDEN YELLOW ANTHYLLIS HERMANNIÆ.

rosy cerise. On the exhibit of Messrs. Stuart Low and Co. we noted their White Pearl, undoubtedly the finest white Carnation to date. Here, too, were to be seen the Hon. Nita Weir, which is said to be an improvement on Enchantress Supreme, both as regards colour and lasting

salmon. This is a very vigorous Rose which should find its way into every garden. The Rev. Pemberton had a small exhibit in the orchid annex.

There were several exhibits of greenhouse plants. The largest was that of Messrs. Russell and Co.,

Turnips, Peas and various saladings. We understand that funds are urgently wanted to enable further training centres to be opened. The hon. secretary is Mr. C. E. Rose, 23, Daleham Gardens, Hampstead, N.W.3.

NEW AND RARE PLANTS.

Anthyllis Hermannia.—This is a pretty shrublet like a miniature Broom smothered in golden yellow, evil-smelling flowers. It has only recently been discovered that the plant is hardy—at least in most districts. Shewn by Mr. W. Wells, jun.

Campanula persicifolia Ryburgh Bells.—This is a very handsome pale lavender form with widely expanded bells. A tall, strong grower, this should make an excellent companion to the deep-coloured Telham Beauty, which in some respects it resembles, but the blossoms are more widely expanded. Award of merit. Shewn by Messrs. George Stark and Son, Great Ryburgh.

Carnation (Border Mrs. Groom.—Presumably, this variety received an award on account of its uncommon colouring—a shade of salmony terracotta. It is not everybody's flower by any means, for the colouring is strident and it would need a bed quite to itself in the garden. The blossoms are of fairly good form and good average size. Award of merit. Shewn by Mr. G. R. Groom, Stoke Road Nurseries, Gosport.

Delphinium Advancement.—This should be a fine back row plant. The very lengthy spikes are pyramidal in shape and very loosely arranged—too loosely, we suspect, for the Committee. The flowers are rosy heliotrope with guard petals of bright azure. The spikes shewn were from one year plants, and it will probably receive the A.M. when next shewn. Exhibited by Messrs. Hewitt and Co., Solihull.

Delphinium My Lady.—This is a medium grower with an exceptionally handsome spike of large shapely flowers, the colouring soft lavender toned with rose. Award of merit. Shewn by Mr. F. Gifford, Hornchurch.

Delphinium Sylph.—A shapely white sort. The newly expanded blossoms are tinged with green, but they pass off pure white. As white Delphiniums go, this is a very good one. Award of merit. Also from Mr. Gifford.

Irish Kämpferi Pyeford Gem.—A variety of moderate size with a good broad fall which, however, as shewn appeared rather lacking in texture. The standards are plum colour, the falls white, heavily reticulated blue and purple—usually purple on one side and blue on the other! Shewn by the Right Hon. Viscount Elveden.

Vuylstekeara insignis picta.—This trigeneric hybrid, produced by crossing *Miltonia Bleuana* with *Odontonia Charlesworthii*, produces a shapely spike of flowers of which the principal colouring on sepals and petals is chocolate plum edged with white. The lip is paler, more broadly edged, the crest orange. Award of merit. Shewn by Messrs. Charlesworth and Co.

[The Report of the National Rose Society's Provincial Show at Saltaire is, owing to pressure on space, held over for our next issue.—Ed.]

FORTHCOMING EVENTS.

July 24.—Royal Horticultural Society's Fortnightly Meeting.

July 25.—Mitcham, Tooting and District Horticultural Society's Meeting.—Guildford and District Gardeners' Association's Exhibition.

July 26.—Royal Botanic Society's Meeting.—Saffron Walden Horticultural Society's Show.

THE PURE WHITE CAMPANULA SPETCHLEY.

This, with a few pieces of rock and some Thymus Serpyllum, formed Mr. E. Dixon's attractive exhibit.

qualities; and Eileen Low, an excellent deep salmon variety. Messrs. Allwood Brothers had an extensive exhibit of Perpetual-flowering and Perpetual Border varieties. Of the former we noted excellent blooms of Edward Allwood, which is claimed to be the premier scarlet Carnation, and Mary Allwood, cherry salmon. Jessie Allwood is a deep yellow Mahmaison. Immediately opposite this exhibit the same firm staged their now greatly improved Allwoodii in great variety.

The National Carnation and Protea Society held the first of its two shows in conjunction with the R.H.S. In the numerous classes Mr. J. Douglas, Miss Shiffner of Lewes and Mr. H. A. Knapton of Orpington were the principal winners. On the whole the blooms exhibited were very good, but there was little competition. Mr. James Douglas was the only one to stage a trade exhibit. We noted The Grey Douglas, which is a large flower of deep heliotrope colour with a silver sheen; Viceroy, yellow ground, edged and streaked deep carmine crimson; Melanie, apricot self; and Glean, an excellent yellow self.

There were only three exhibits of Roses, this no doubt being due to the provincial show at Saltaire of the National Rose Society. Messrs. George Bunyard and Co. shewed many varieties, including Isabel, a beautiful orange scarlet single; Lania (H.T.), reddish orange; Independence Day (Pernet.), deep orange, an excellent bedding Rose; Golden Ophelia (H.T.), a delightful yellow Rose the petals of which are cream coloured; and Golden Emblem (Pernet.), the well known and excellent golden yellow sort. Much interest was shewn in the old Damascus Rose des Peintres, which, although not beautiful, is delightfully and sharply scented. Some of the blooms in this exhibit shewed the effects of the drought, but on the whole they are of outstanding quality. Messrs. Frank Cant shewed excellent blooms of such varieties as Golden Ophelia, Mme. Abel Chatenay, pale salmon pink with deeper centre, still one of the finest garden Roses; Red Letter Day (H.T.), scarlet crimson; and Lady Pirrie (H.T.), coppery

who had numerous varieties of Crotons and Caladiums. Here we noted a very fine specimen of *Medinilla magnifica*. This is an evergreen shrub for the stove hailing from Manilla and producing rosy pink flowers in very large pendulous terminal racemes. Mr. R. Arnold of Streatham had a large exhibit of beautifully coloured Caladiums. Messrs. J. Cheal and Sons, in addition to their herbaceous plants, shewed many of their now famous Star Dahlias. Here we noted White Star, Crawley Star, clear rose pink (the first Star Dahlia introduced by the firm), and Yellow Star. Apart from their garden value, these "Stars" are excellent for cutting purposes. Petunias in many colours were well shewn by Messrs. W. Hopwood and Son of Cheltenham Spa.

Messrs. R. and G. Cuthbert of Southgate staged some excellent *Streptocarpus* in white, mauve, pink and blue shades. These were interspersed with foliage plants. There were only two small groups of Orchids and these were exhibited by Messrs. Sanders and Messrs. Stuart Low and Co.

In the competitive classes for Cherries there was only one exhibit for the Bunyard medals; this came from Sir C. Nall Cain, whose six dishes included Kentish Bigarreau, May Duke and Duchesse de Palluan. Two very fine trade exhibits, however, came from the Sittingbourne district. These were shewn by Messrs. Deane and Co., Limited (Silver-gilt Hogg medal), and Messrs. G. Webb and Son (Silver Hogg medal).

Messrs. Gill and Son of Rhododendron fame shewed a new Strawberry called Gill's A 1. This is a cross between Royal Sovereign and Mme. Kooli. The fruits are exceptionally large and of irregular shape. We did not have the opportunity of testing this variety, so cannot speak as to its flavour, but the aroma was excellent. It is certainly not a pretty fruit.

The only exhibit of vegetables came from the Guild of Blind Gardeners. The vegetables shewn, which were very creditable, included Potatoes,

SPECKLED FOXGLOVES—AND OTHERS

ARE there people, I wonder, so consistently fond of gardening that their gardens never bore them? If so, I am not one of them, for there are times when mine grows unbearably stale; and, curiously enough, those times are not in the dreary months of winter nor yet in the nipping spring, but in the full tide of summer when everything is lush and lusty. Nor, unfortunately, can I always keep my discontent to myself, but must grumble it into Robin's ears (Robin being youthful successor to Christopher, many of whose virtues he possesses, with points peculiarly his own). "Life might be worth living were it not for this blessed garden!" I say, as much to myself perhaps as to Robin, when the spiritual barometer is low. "If you wish to be happy, Robin, take care never to possess a garden of your own—with its eternal weeding and sowing and hoeing and mowing and staking and its 365 disappointments per annum. Rather, if you can, rent a cottage close by the gates of Kew, where you will have a capable staff to save you all trouble. If you cannot manage Kew, squat beside some other garden, where you can have the delights without the worries and disappointments. For the disappointments of other people, Robin, are comparatively easy to bear, though of course if we were good Christians, they ought not to be." For one so young, Robin has a wonderful faculty of discreet silence; but his sapient smile, which I have learned to read like print, tells me candidly enough just how seriously he takes these plaintive explosions. Young as he is, the boy has discovered for himself that life is not all "beer and skittles," and he knows full well, besides, that, if it were, both the beer and the skittles would lose their consoling savour. And Robin is right; so they would. Still, there it is—there is no use denying that a garden gets at times to be an "Old Man of the Sea," which one would gladly shake from one's shoulders for a spell if one could. When you feel like this about your garden, take sound advice

and quit it if you can, as I quitted mine for a fortnight early in June, a tolerably quiescent time of the year for most gardens: Tulips over; Irises not yet fairly on the move (though Lord of June is raising lovely standards and Prosper Laugier is spreading its wine-red falls); here and there a Foxglove reddening its thimbles; Paony knobs shewing seams of colour; and forests of Poppy heads, not yet burst, but plump to the point of bursting. At this time Nature does not seem particularly alert, though she is not slacking, as you might erroneously suppose—busy, rather, preparing for her crowning achievement, the big burst of summer. Meantime, however, she seems to pause (possibly to some extent she actually does pause, but it is only to recoil for a better leap). Anyhow, there is a temporary lull in the colour pageant of the year. Then is the time for a run to town and a fortnight's surfeit of bustle and sweet sound—Melba, Elman, Paderewski, Chopin, Tchaikovsky, Holst—and so back again, replete, to shoulder once more the "Old Man of the Sea," and just in time to witness the midsummer transformation scene.

In early June I left the garden marking time, after its unparalleled display of May Tulips. I found it on my return a wilderness of colour, unbelievable as the output of one short fortnight: Delphiniums, Paeonies, Marigolds (superb), Lupins (on the wane), Irises (but the germanica race below par), Rock Roses, Nigellas, Poppies, Mock Oranges, Deutzias (various, single and double, snow white and exquisite), jungles of Anchusa as blue as indigo, and (unobtrusive, but welcome sight) *Herba-barona*, bristling with flower-heads, an indubitable Thyme. As for climbing and rambling Roses, they crowded overhead with tropical extravagance, and not only overhead, for the ground also was thick petalled underfoot. But of all the things that clamoured for attention perhaps those which clamoured loudest were the Foxgloves, about which flowers I had to take my bearings in order to find exactly how I stood;

This year I have grown four strains of Foxglove: (1) My own strain, if strain you can call what has gone on, year after year for a decade, sowing itself without any process of selection or elimination except that exercised by the slugs and an indiscriminating hoe. (2) The Munstead strain, the distinction of which I understand to be a pure white flower entirely free from throat-spots. If this is the standard aimed at, my experience of the Munstead Foxglove enables me to say that the strain is well fixed. Among my many Munstead plants I find only two rogues, a purple and a light pink, both with throats more or less densely speckled. But in my own primeval strain I have found in various parts of the garden Foxglove spires, half a dozen at least, indistinguishable from those of the Munstead plants—the same habit, the same white colour, and the same absence of throat spots. Therefore, I cannot see the relevancy of a "Munstead strain" for what comes unsought in an ordinary garden; unless, of course, one wishes his Foxgloves to be all of them white and all unspotted, in which case I can with confidence recommend the Munstead flowers. I like these flowers myself, and should always wish to have them in considerable numbers. But my heart's desire in Foxgloves is neither white nor unspotted. It is rather a flower with a densely speckled throat—spots of all sizes from a pin-head to a pin-point. As to colour, though I like white very well, I wish my Foxgloves to run through the whole *Digitalis* gamut, from the purple of the sylvan *purpurea* (a shade which would hardly be tolerable in anything but a Foxglove) up through various light purples and pinks to absolute white. The range is not so extensive that we can afford to forgo any one of the shades. We want our Foxgloves as tall and stately as possible, and the "gloves" as large as we can get them, not overcrowded, but arranged in that lovely honeycomb fashion so characteristic of the flower. We further desire as large a range of colour as we can get, and we especially want our Foxgloves boldly spotted. At least I do. And I fancy that something like this was the ideal the late Rev. W. Wilks set himself when he tried to do for the Foxglove what he had already done for the Field Poppy: which brings me to strain No. 3—the Shirley. From my own plantation of Shirley Foxgloves I conclude that Mr. Wilks was on the way to achieve what he proposed to himself, but had not quite reached his objective. I have no doubt that had he lived for a few years longer he would, by his patient and intelligent system of selection and elimination, have established a strain which all flower-lovers would have desired to grow. As it is, if my own Shirley flowers fairly represent the strain, I cannot think that anything much out of the way has so far been achieved. "Good," but not "supreme" would be my verdict; by which I mean that the flowers, though good, are not equal to what I conceive to have been the Wilks ideal. Some of the throats are finely spotted, archipelagos of crimson islands on a ground of cream and pink. But otherwise, as regards vigour, habit, or range of colour, there is nothing remarkable about the flowers. On the whole I see no convincing reason for rooting out my own haphazards in order to make a fair field for the Shirley strain, though I hope that the new blood introduced may improve the general quality of the Foxgloves in my garden. Presently, no doubt, some capable hybridist will take in hand and complete the task which Mr. Wilks had so well begun.

Strain 4 is, strictly speaking, not a strain, at least I think not, but a species. I had the seed last year as that of "Sutton's Primrose Giant," the catalogue description giving the shade as "cream" or "buff." The shade is not easy to

THE STATELY FOXGLOVE.

name, but it is nearer to primrose than to cream or buff. Anyhow, it is clear and charming. Gargantuan flowers are not, rather of medium size, but this has not been a season for giants. Altogether this is a handsome Foxglove which I am glad to have and which I hope to keep now that I have it, though, in my garden, species are not easily kept intact. A group of some score of spires of the Giant Primrose, if not the most beautiful, is certainly the most interesting subject I have at present in the garden, especially when the evening sun shines through the flower. Then it becomes a super-Digitalis. I take this species to be *Digitalis lutea*. It is certainly not *grandiflora*.

I am this season, I suspect, somewhat Digitalis-ridden, which may be the reason why my prophetic soul sees such great things in store for the Foxglove in the near future, when the destined hybridist takes the flower in hand. He will have at least a score of species to work upon; and though many of these, perhaps most of them, are of little except botanical interest, we know that species, possessed of little beauty in themselves, may be potent to modify other species in desirable directions. In any case it is to be hoped that the hybridist of the future will eschew such fasciated abominations as the Foxglove now known as *Digitalis monstrosa*.
SOMERS.

CORRESPONDENCE

ROSA HUGONIS.

OUR experience with this Rose in the present season corresponds with Mr. Jacob's. Plenty of buds on the point of expanding, but not a single full-blown flower. Here it has never behaved like that before; I suppose it must be set down to the account of the cold, dark summer of 1922, the effect of which has been so apparent in deficiency of blossom on many plants, from Horse Chestnut down to Bearded Iris. On the other hand, *Rosa Moyesii* is a furnace of bloom, and its rose-coloured variety *Fargesii* is also full of flower. It may be noted that no vicissitude of season affects the display on any species of *Olearia* or *Leptospermum*; not, at least, on any of the species grown here. *Olearia nitida* throughout May has been followed by *O. macrodonta*, *ilicifolia*, *stellulata*, *semi-dentata* and the dingy *O. Traversii*, after which no doubt *O. nummularifolia* and *Haastii* will take up the running with their accustomed profusion. Of the *Manuka*, *Leptospermum scoparium* and its crimson variety *Nicholii*, *lanigerum* and *ericoides* are, if possible, more fully set with bloom than usual.—HERBERT MAXWELL, *Monroville*.

TWO PRETTY EDGE PLANTS.

THOUGH the accompanying illustration does faint justice to that beautiful form of *Veronica rupestris* known as var. *Treherne*, the constellation

of daisy-like flowers will be recognised as those of *Vittadenia triloba* (*Erigeron mucronatus*). Both of these are excellent plants for the front of a dry, sunny border or the rock garden, and together they make a brilliant mass of colour from early summer for many weeks. Indeed, the *Vittadenia* is an all-season bloomer, and its bright little golden-eyed flowers, which open pink and pass off into white, are produced in amazing prodigality. In some gardens this plant seeds rather too freely, but the stray seedlings are easily uprooted when young. The *Veronica* is not only quite as free a blossomer as the typical form, but its flowers are, individually, larger than those of the latter, rather a paler blue, and they enjoy the advantage of being accompanied by a foliage which is a clear yellow during the flowering season. This is not only a plant of the highest merit, but it is undoubtedly one of the choicest and most distinctive of all the trailing *Veronicas*.—NORTH WALES.

CLOVER AS A LAWN PLANT.

THERE is a good deal of truth in what your contributor "S. P." says, but most people would admit that drifts of Clover meandering haphazard over a lawn of an entirely different colour present a terrible appearance. We have a fair amount of it on the lawn here, but it is similar

in shade to the grass and is not very noticeable. I have not found that it stands drought much, if any, better than grass; if the grass burns up, clover does the same. In most gardens the reverse seems to hold good; but the modes of establishing it on lawns detailed by "S. P." are hardly to be recommended. Lawns consisting chiefly of Clover, if they are to look well, require as careful production as all-grass lawns. I am not aware that there is any difficulty in persuading it to establish itself evenly if it is sown evenly when the lawn is first being formed; but who could expect it to look otherwise than patchy if an attempt is made to introduce it on an already existing lawn? At its best White Clover produces a dappled effect that is not unpleasing, even though it is not nearly so beautiful in colour as grass. (In saying this I am disregarding "S. P.'s" preference, which is abnormal.) Why use it, however, when the yellow variety is so much better? Its colour is much nearer to grass than that of White Clover; its leaves do not hold moisture after rain as those of the white sort do; it stands drought and hard wear as well or better, and in its perennial character and general constitution it is the equal, if not the superior, of White Clover. There appear to be only two considerations which militate against its general use, the first being that nobody knows about it, and the second that it is (therefore, possibly) difficult to get hold of. The first of these drawbacks you, sir, might do something to dissipate; as regards the second, I believe Messrs. Rowntree of St. Albans supply it—I know they used to, and while I have not seen any very recent catalogue of theirs, I presume they still do so.—K. A. BAYNE, *Oulton, Birkenhead*.

DITTANY OF CRETE.

PROPOS "Caledonia's" note (page 336) on that nice old-fashioned herb the Dittany of Crete, of which Turner, in his *Herbal*, 1568, says, "I have seen it growyng in Maister Riches garden naturally, but it groweth nowhere else that I know of saving only in Candia," it used to be a favourite with the cottagers in Kent, but not having seen it for many years I was pleasantly surprised to find it happy and at home on a wall top in Glasnevin Botanic Gardens last year. Kentish folks used to call it the Hop Plant from the resemblance of its inflorescence to that of the Hop.—K., *Dublin*.

FRAGRANT FOLIAGE.

WILL you permit me to thank various correspondents of THE GARDEN for their kindly and helpful comments on my articles on "Fragrant Foliage." Some of them have obligingly introduced me to other plants with scented leaves which, though known to me by name, have not hitherto been cultivated in my garden. I should be glad to know, from someone who grows them, about the Basils: which of the two is best worth growing for its scent? Bush Basil (*Ocimum minimum*), I suppose. It is an annual, and therefore I should not expect to list it permanently among my sweet-foliaged plants. But I should like for once to possess a "pot of Basil." The Common Hyssop, though generally regarded as a kitchen or medicinal herb, has a place of honour in my garden. To my sense it smells as strongly of camphor as the Camphor Tree itself. Further, I know no plant which attracts so many butterflies and other flies of various kinds.

Mr. Warner's remarks on the keenness of the sense of smell in insects are of special interest. I was aware, of course, that insects possess a sense analogous to our sense of smell. The house fly and the carrion flies are sufficiently convincing proofs of this. I had not realised, however, that

VITTADENIA TRILOBA AND VERONICA RUPESTRIS TREHERNE.

the sense played quite so significant a part in the life-economy of insects as Mr. Warner shews to be the case. Mr. Warner will, however, pardon me, I hope, if I say that I fail to gather from his otherwise interesting and instructive remarks any adequate explanation of the fact (if it is a fact) that the Labiate Order contains a larger proportion of plants with fragrant foliage than most, if not all, other Orders. That "flowers with a lip are specially contrived to attract insects" and that "the flowers are beautiful but complex machines to secure cross-fertilisation" is true, no doubt. But if labiate flowers are so wonderfully

to shew that smell is an important sense in insects and that certain flowers of the labiate family, for instance, have this or that odour agreeable to insects. What one wants to know is the correlation of labiate flower-structure and fragrance of leaf which so frequently makes the one go with the other.—SOMERS.

IRIS BLACK PRINCE.

HAVING seen your appreciative remarks with regard to Iris Black Prince, I am venturing to send you a photograph of this plant as I saw

IRIS BLACK PRINCE, WITH BLACK VIOLET FALLS.

contrived for purposes of cross-fertilisation, why should an Order, the flowers of which are so fortified, have in addition fragrant foliage to a greater extent than other Orders. If I am right in trusting to my own experience that labiates have, to a larger extent than other Orders of plants which we cultivate in our gardens, leaves that emit a perfume agreeable or disagreeable to the human sense of smell, any explanation of the fact must consist, I should think, in shewing that the labiate structure of blossom and the perfume of the foliage act and react on each other in such a way as to facilitate the fertilisation of the plants. Is there, then, anything in the structure of labiate flowers (a deficiency of perfume, for instance) which requires that some lack in the bloom should be supplied by fragrance in the leaf? This might account for the prevalence of fragrant foliage in labiates. But, as far as I remember, the flowers of such labiates as have fragrant foliage are not specially deficient in scent. I have just been experimenting with Lemon Thyme and Herba-barona, and find that the blossoms smell as strong as the leaf. This is true also, I think, of the blossom and leaf of Rosemary and Lavender. The blossom of Catmint (*Nepeta Mussini*) if held to the nose gives its characteristic perfume but slightly. The leaf emits no perfume except under pressure. Both leaf and flower when rubbed emit the strong odour which gets the plant its name. So I must still ask, I am afraid, why so many members of the labiate Order in particular have their leaves strongly perfumed. It is not sufficient, I venture to submit to Mr. Warner,

it, some years ago now, growing at Mr. Perry's nursery. I think it makes a pleasing picture even in black and white, but one has only in imagination to supply the velvety blue-black of the falls with their violet edging and the much diluted violet of the wings to realise the splendour of the flower. Mr. Perry, I know, considers this the best of the pallida and Cengialti crosses to date, and I thoroughly agree with him.—H. C.

THE GARDEN LEAGUE FOR DEVASTATED FRANCE.

WE are anxious to bring to the notice of readers of THE GARDEN our appeal for The Garden League for Devastated France (*L'Œuvre du "Jardin de la France Dévastée"*), which has carried on its work quietly and most effectively in the ruined area of France since early 1920. With a view to making the society better known in this country—as it was intended from the first that it should owe its support to our garden lovers whose ground was spared to them—a British Committee of the League has been formed this year. The following are a few facts concerning the above-named League, which is registered under the War Charities Acts of France and England. It is a society on Franco-British lines, whose practical work for the restoration of garden ground was founded and is carried on by a trained woman-gardener supported by Franco-British Committees and with the special approval of the French Government (represented by the Ministère des Affaires Étrangères, Ministère des Régions

Liberées, Ministère de l'Agriculture and Ministère de l'Instruction Publique et des Beaux-Arts) and of the Préfectures of the devastated departments of France. Its patrons are Their Excellencies the British Ambassador in Paris and the French Ambassador in London. The president of the British Committee is Major-General Right Hon. J. B. E. Seely, C.B., C.M.G., D.S.O. Lord Lambourne and Mr. Rudyard Kipling are vice-presidents of the League, which numbers among a long list of distinguished supporters in this country the Right Rev. Herbert Bury (Anglican Bishop for North and Central Europe), Viscount and Viscountess Burnham, Lady Maud Warrender, Sir Capel Wolseley, Bart., and Lady Wolseley, Sir Harry Brittain, M.P., and Lady Brittain, Mrs. Wintringham, M.P., Sir Frederick Keeble, Miss Gertrude Jekyll, Miss Ellen Willmott, and the firms of Sutton and Sons, James Carter and Co., Robert Veitch and Sons, R. W. Wallace and Co., etc.

The Garden League has already helped and encouraged (with the official co-operation of the French Inspectorate) 250 school gardens, as well as hundreds of other ruined vegetable and fruit gardens, where lack of tools and other necessities had sometimes made impossible a fresh start on this shell-scarred ground. British school children are "adopting" these school gardens and sending them gifts through the League. It has already given more than 1,200 garden tools, very large quantities of vegetable seeds, and also medicinal and other plants, besides over 1,000 fruit trees—chiefly "formed" trees for present bearing. It stimulates the teaching and practice of good gardening and helps to start gardens in conjunction with social work, which the misery of life in the devastated regions makes especially valuable. It helps, where possible, to restore the gardens of the societies of horticulture in such cities as Reims and Verdun, which, unlike our own, were destroyed by the war. Lastly, and best of all, the Garden League helps to cement a lasting friendship, more particularly through their children and young people, between the French and English speaking nations, whose blood was mingled in the cause of Right and Liberty. In this connexion we record with special pleasure the keen appreciation, shewn by the French Ambassador, the Comtesse de Saint-Aulaire, for our work in its dual aspect in France. Writing from the French Embassy in London, Her Excellency expresses her personal thanks for what has been accomplished and continues: "I have heard from so many people the beautiful work you and your Committee have carried out in the devastated regions, and I cannot prevent myself from telling you my own admiration. Your work has not only been a material one, but it also helps to bring more and more together our two nations. By sending seeds and fruit trees the children of England prepare the best harvest of gratitude, and you will have helped to draw closer that brotherhood which was born in the war and which must always bind England and France."

Will readers of THE GARDEN help the needy funds of the Garden League for Devastated France in order that it may carry on its good work for the real *entente*? Contributions in money, in kind and in personal service entitle to membership. A minimum subscription of 2s. 6d. is welcomed from those who cannot contribute large sums. Collecting envelopes for amounts of 10s., 20s. and upwards gladly provided. Schools will be brought into touch with a French school garden needing restoration or help. Offers of seeds, tools and fruit trees will be received with pleasure. See address at foot of letter, from which further information may be obtained as

to ways of helping by voluntary service, propaganda, etc., whether in England or France. The League has, at the time of writing, a temporary office in England at 31, Upper Berkeley Street, W.1. (Tel. Paddington 6097). HELLIS COLL.

Founder and Hon. Organising Secretary, The Garden League for Devastated France.

Le Jardin de la France Dévastée, Ministère des Affaires Étrangères, Bastion 55, Paris, XVI. (Tel. Passy 77-53 and 85-70.)

ROUND ABOUT A JULY GARDEN

TOWARDS the Campanulas at this season one always has a feeling of gratitude, because they break into flower just when so many things are going off and when the first symptoms of shabbiness begin to invade the spring freshness of rock garden and wall. Then there is their simple charm, their winning grace, and that tone of refinement which pervades most of them, more especially the little fellows.

Indeed, there are few flowers in the long round of our garden year so appealing as those Bell Flowers of the *pumila* and *pulla* classes. Whether these are threading the crevices of one's dry wall, making neat little mats of colour on the rock garden ledges or filling the chinks and angles of the steps, they are always cheerful and surpassingly lovely. One can hardly differentiate between such treasures as these, but many of us will have a very special regard, perhaps, for *C. pumila*. Miss Willmot in a gentle azure and the pure white form of the same thing. Then there is *Miranda* with larger and rounder bells, a cool smoke blue and, in a deep and lustrous violet, the delightful *C. pulla* G. F. Wilson, which is peculiarly fascinating.

Other Campanulas there are in plenty, but for the moment the above are among those most in evidence among the dwarfs. One cannot, however, pass by that ramping beauty, *C. Raddeana*, whose big violet bells are usually the very first to open, nor that good old stand-by, *C. Portenschlagiana*, and those of the select little *garganica* set. All of the last mentioned are first-rate wall plants excepting, perhaps, *W. H. Paine*, whose navy blue is accentuated by the distinct central zone of white. The form *albus* of *C. g. hirsuta* and *C. g. erinus*, of which the starry flowers are a deep periwinkle blue, are also special favourites here.

The manner in which some of the *Linums* continue to produce their countless flowers day after day throughout the mid-summer months, and this on a diet of dust-dry grit and what sunshine the gods vouchsafe, is an eternal source of wonder and admiration. *L. narbonneense* is probably the most surprising in this respect, its masses of clear yet bold blue, often a yard across, being renewed every twenty-four hours or so without the slightest symptom of failing vigour. *L. arborescens* has this year been hardly less prodigal of its wealth of glistening gold, and *L. monogynum* will not cease to yield its snow white heads of blossom until autumn comes, despite the fact that it is a more prolific seed-bearer than most. *L. salsoloides*, if less vigorous, is another constant bloomer from July onwards, the icy whiteness of its elegant blossoms being most delicately shaded with a pearly lustre. The prostrate form of this Alpine Flax is very choice and distinct, and another charming plant which bears no little affinity to the last, save that its flowers are a pale turquoise like those of *perenne*, is *L. collinum* (?).

The Daisy tribe is not notable for varieties which excite uncommon interest, but there is one which is a little gem, and that is *Belis cornulescens*. This is said to be a form of *B. rotundifolia*, but can claim not only specific distinction but a rare beauty of its own. The leafage of this dainty thing comprises a compact rosette of silky, grey-green foliage from which

springs up throughout the summer a succession of Daisies which are in size and form almost exactly like our own wilding, but their yellow centres are fringed with rays of that most refined and cool lilac blue one associates with the Caucasian Scabious.

Near the above *Verbena radicans* is creeping with wiry stems and dark green, leathery leaves over the dry, well drained soil, putting up at intervals a closely clustered head of purple flowers. Some of the Prickly Thritts are also happy under such conditions, the spiny cushions of *Acantholimon glumaceum* being gay with rosy pink blossoms. This well known species is soon followed by the choicer and more uncommon *A. venustum*, with greyer leafage and taller flower-stems, which stand up above the leaves in elegantly curved sprays of larger flowers in a brighter, fuller pink. This delightful little plant has proved as steadfast here as the preceding.

Always reliable on the driest of ledges is *Hippocrepis comosa*, the Horse Shoe Vetch, a precious native of our limestone cliffs, which throughout July will cover the sombre green with which it drapes the rock or shelving bank with numbers of little circlets of gold. This has never erred from the straight and narrow way with us by trespassing, as do so many of its pretty but wanton relations, nor do its horse-shoe seed-pods produce any offspring. Bigger and bolder, but not better, is a southern legume, *Coronilla cappadocica* (iberica), which enjoys any sun-beaten slope, covering it with a loose tin. mat of glaucous foliage which is adorned throughout the latter half of summer with handsome coronets of gold.

It is at this season that we can most willingly forgive that pretty pest, *Oxalis obliqua* (which I am told is its right name) for being a very murrain at others. Its large, drooping bells in a lively rose-purple are extremely attractive, and the olive green, luscious foliage, with crescentic markings in maroon, is worthy of them. At other seasons, however, one may as well make a virtue of a necessity, for once this charming scourge develops a liking for you no human agency will extirpate its swarming legions. Another *Oxalis* which must be the midget of the clan, since one can hardly conceive any plant of smaller dimensions, is creeping in a faint film of palest green over some hot, gritty soil. The lobes of its tiny trefoil leaves, which are as depressed as those of *Mentha Requienii*, are no larger than the head of a pin, while from the hair-like stems is put up at intervals a yellow upright flower not much above one-eighth of an inch across. This wee straying I cannot identify, and its origin is as obscure as that of the scarecrow in the fable.

The Hypericums are at their best in July, and reptans and *olympicum* are competing one with another in a blaze of gold for the supreme honour of being the "best" of their class. Be that as it may, I will risk being considered pedantic by saying that I would sooner have *H. Coris* than either of the above were I ever doomed to possess but one species of this dazzling race, for there is a grace and airy lightness about the latter which is very fascinating and distinct. *H. Coris* is, moreover, a plant of commendable refinement, for as one by one its galaxy of golden stars pass away, there are no messy remnants left behind

to mar the beauty of those to follow, which is more than one can say of some of its more gaudy neighbours. Even in winter its fine, healthy foliage never looks shabby. Of *H. repens* much might also be said, for this is a cheerful thing at all seasons, the wiry, moss-green foliage covering the ground like some prostrate Heath. The tall, upright flower-spikes of *H. repens* produce a long succession of bloom in a good firm yellow which has not the characteristic dandelion burnish of so many of these little sun worshippers. *H. fragile* and *H. nummularium* are both admirable and distinctive, but plants bearing the name of the latter are by no means always the right thing. Nor can one pass by the delicate grace of sweet little *H. cuneatum*, whose ruby buds break out into orbs of gold which seem so absurdly large for so small a plant.

Though the earlier Pinks have completed their round, there are still plenty left, and these mainly comprise a swarm of pretty mongrels which might not be permitted to usurp so large a part of one's rock garden, wall and edgings did they not so cunningly win one's affection by their happy, contented natures and delicious fragrance. *Neglectus* and *caesius*, *superbus* and *alpinus*, *deltoides*, *zonatus* and many another have all lent something of their beauty and charm to this cheerful throng. A very shaggy little Russian fellow in a dead white and whose dreadful name I have forgotten is one of the most fragrant. But it is mainly to the *superbus* influence that one is most grateful for the majority of those many fringed Pinks whose cool shades of colour, which range from white to pale lavender and blush, will be no less welcome throughout the later summer than the perfume which they so generously distil. The great sheaves of clear rose blossoms produced by *D. Fettes Mount* are also as rich in their old clove scent as they are good and pure in colour, and another hybrid of medium stature whose very large, single, rose pink flowers with a blood crimson zone are very highly perfumed is *D. Gladys Cranfield*. A good strain of *D. striatiflorus* in a soft shrimp pink is an all-season bloomer of old repute, and one only wishes that some of its near relations of the hybrid *barbatus* set were one-half so permanent and reliable.

North Wales.

J.

STRAWBERRIES FOR FORCING AND NEW PLANTATIONS

Some Simple Methods of Layering.

IF the runners are healthy and substantial, they cannot be layered too soon in July, either for growing on in pots, for forcing, or for the formation of new plantations. The runners on plants that have fruited one year only are the best, and they must be the first plantlets formed on the runners, not the second or third. Some runners bear even four, but the one nearest the parent plant is the best; all others should be cut off. Of course, runners on two and three year old plants may be used if they are strong and healthy, and there are not many obtainable on younger plants.

For all purposes small pots may be used for the layering; those commonly called "large sixties"—3½ ins. across—are best. The most useful compost is one formed as follows: fibrous turf, two parts; horse manure from which all rank gases have been expelled, one part. Where this is unobtainable, then use good loam as fresh as possible, but in which the grass and its roots have died, and a small quantity of rotted manure

Do not add sand, as Strawberries do not thrive so well if sand is added as without it.

The runners from two rows of plants should be gathered neatly together in the space between the rows and be denuded of all surplus plantlets. Three parts fill the pots and firm the soil in them; half bury the pots in the ground to ensure steadiness, place a runner on the soil in the pot and a flat-shaped stone on it. Stones are better than pegs, as they maintain some moisture under them and hasten the formation of new roots in the soil. Apply water through a rosed watering-can and afterwards frequently if the weather is dry. When the young plants are sufficiently rooted, cut off the stem, severing it from the parent plant, and

transfer the pots to the north side of a wall or fence, leaving them there for a week or so to allow the plants to become established in them. Syringe once every day, twice in hot weather. If some are required for growing in pots to be eventually fruited in them, a selection of those possessing the plumpest crowns should be made. They may be repotted direct into these pots—5 in. and 6½ in. ones—and placed in a very sunny position throughout the autumn months to get the crowns plump and leaves matured.

Those for the new plantations should be planted out as early as possible, as such early established plants always yield the biggest crops and the finest berries. G. G.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Celery.—The final planting of Celery should take place without further delay, and the earlier crops be earthed up as the necessity arises. The trenches should be cleared of weeds, side shoots and decayed leaves, and if the soil is at all dry a thorough soaking given the night previous to earthing up. Before commencing operations draw the leaves carefully together and tie them with raffia or any similar material, which should be removed after the soil has been set in position. Care should be taken to prevent the soil entering the hearts or centre of the plants.

Lettuce.—A liberal sowing of Lettuce should be made for use during late autumn and early winter, selecting both the Cabbage and Cos varieties. Continuity, Hicks' Hardy White and All the Year Round are reliable kinds. The soil should be in good condition, and when the seedlings are large enough a liberal thinning should take place and some of the young plants be transplanted in lines 1 ft. apart.

Spring Cabbage.—This is a most important crop, and everyone is anxious to secure good sound hearts as early as possible in the spring. I do not recommend a large sowing at this date, but a little seed sown now may produce an early crop next year. The main or principal sowing should be deferred until early in August. Last year we grew April, Ellam's Early, Imperial and Flower of Spring, and with the exception of April, which was a few days earlier, there was little to choose between them. The seeds should be sown thinly in lines 1 ft. apart and transferred to their final quarters when large enough. The small varieties, such as April, may be set out 1 ft. apart, but the large kinds will need another 6 ins.

Endive.—Another sowing of Batavian Endive may be made for a winter supply. Radishes should be sown, also Mustard and Cress. Keep the whole of the garden free from weeds, and ply the hoe between the various crops.

The Flower Garden.

Carnations.—The layering of Border Carnations should be proceeded with to give them a chance of becoming well rooted before winter sets in. A compost consisting of finely sifted loam, leaf-mould and sand should be prepared and placed around the plant before the operation begins. Select the best and strongest shoots, and any weak, spindly growth may be removed. A few of the lower leaves should be pulled off and a slight longitudinal incision or tongue made with a sharp knife, and the shoot pegged down and lightly covered with soil. Keep the compost moist and in a few weeks roots will form. It is the practice with some growers to pot off the layers later on and winter them in cold frames, but there is no reason why they should not be transferred to their stations in the borders or prepared bed. If the position is empty, it should be deeply dug, given a liberal dressing of manure and sifted lime rubble.

Roses.—In many districts there is a keen desire to secure a few Briars in the autumn and winter with the object of doing a little budding the following summer. Now is the time to do the budding providing the bark works easily; if not, the operation must wait. Select good buds and use a sharp knife.

Antirrhinums.—These charming plants may be had in bloom several weeks earlier than is usual

if the seed is sown at the present time. It will germinate freely in the open ground if the drills are well soaked with water previous to sowing. When the seedlings are large enough they should be planted out where they are intended to flower. The soil need not be rich.

The Hardy Fruit Garden.

Loganberry.—This is probably one of the most useful fruits grown, and it rarely fails to produce a crop, which is a valuable attribute in a season when other fruit is scarce. It is cultivated much more freely than a few years ago, being found in both large and small gardens. The Loganberry is a vigorous plant, and at the present time the new shoots are making considerable headway. After the fruit has been gathered remove all the old growths down to the ground-level and replace them with new canes. Overcrowding must be guarded against, and to this end the weak shoots of the current season may also be cut out. Young growths of Blackberries should be tied up occasionally to prevent them being broken.

Raspberries.—Directly the fruit has been disposed of cut out all the old canes and any young shoots not required for next season. If the soil or mulching material is hard between the rows, it may be lightly pricked over with a fork.

Fruits Under Glass.

Strawberries.—Runners that were layered in pots a few weeks ago will have rooted sufficiently to be severed from the old plant. The pots should then be plunged in ashes until they are ready for their fruiting receptacles. In the meantime keep the roots well supplied with water, and damp them over with a fine-rosed watering can late in the afternoon. Remove all runners as they appear.

Vines.—Where the fruit is ripe the viney should be kept as cool as possible, and plenty of air should be admitted. If the weather is wet, a little warmth from the hot-water pipes is recommended. Wasps are often troublesome, and if they are at all numerous the ventilators should be covered with muslin.

Figs.—Trees that are producing a second crop may be fed with liquid manure or some approved fertiliser, such as "Thomson's" or Le Fructeur. Spray the foliage with soft water whenever the weather is hot, both in the morning and afternoon. Overcrowding of the growths should be prevented and plenty of air admitted. Pot trees should be given a sunny position outside and the roots well supplied with moisture.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),
Castleford, Chelmslow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Onions.—If there are signs of rain, give the crop a final application of nitrate of soda or other quick-acting fertiliser. Those who practise autumn sowing—a system which has much to recommend it—should select a quarter which has just been cleared of an early crop, give it a liberal dressing of organic manure, and double dig it preparatory to sowing the crop in the near future.

Seakale.—In order to produce strong crowns for forcing, Seakale must be accorded liberal

treatment. Take advantage of showery weather to give it moderate dressings of some approved fertiliser. Another light dressing of agricultural salt will also prove beneficial. Stir the soil with the hoe periodically.

Asparagus.—Established plants will be completing their growth for the season within the next few weeks, so advantage should be taken of the least appearance of rain to give the crop another moderate dressing of salt plus a light dressing of sulphate of ammonia or other quick-acting fertiliser. First year's seedlings, if the ground was well enriched prior to sowing, should require no stimulant this season. Keep the whole crop clear of weeds by means of the Dutch hoe and hand-weeding.

General Work.—It is always a paying investment to give occasional light dressings of some fertiliser to growing crops. Of course, those who have on hand dry towl manure, soot or wood-ashes should utilise such in the first place. Keep the Dutch hoe going frequently among crops, as this attention serves the double purpose of aerating the soil and keeping down weeds. If a time of real drought sets in, attend to watering of crops, avoiding the dribble system, which often does more harm than good, luring the roots to the surface. One copious watering will generally tide over any period of drought in Scotland.

The Hardy Fruit Garden.

Apricots.—As the ripening period draws near it is essential that the fruits get the benefit of the fullest possible amount of light. Remove, therefore, any leaves or shoots that obstruct the sun's rays. Make sure that the trees have sufficient moisture at the root, and if found to be deficient, give sufficient water thoroughly to wet the entire mass of soil and, thereafter, stir the surface with the hoe, for if the trees are short of moisture at this stage the fruits will lack that juiciness which is essential to really good quality, and a portion of them are likely to crack.

Peaches can only be grown successfully in the more favoured localities in Scotland, and even in those only in fairly good seasons. Strict attention should therefore be given to the trees. Nail or tie in succession shoots and otherwise give them the attention recommended for apricots.

Strawberries.—Runners that were layered last month—especially those layered in small pots—should not be allowed to suffer for lack of water, as the least check to the plantlets will tell against their cropping powers next season. As early crops get cleared off, a quarter should be well manured and either trenched or double dug, so that the soil may have time to settle down before planting-time, which is now near at hand. Strawberries, in common with other fruits, should be picked when dry; this is even more imperative in the case of fruit that is to be used for preserving.

The Flower Garden.

Carnations.—No time should be lost now in getting sufficient stock layered. The *modus operandi* is comparatively simple. The operator, having furnished himself with some receptacle filled with a sandy compost, a handfork or trowel (the former for choice) and a sharp knife, should slacken and scoop out some soil underneath the shoot to be layered. The knife should then be inserted in the stem about a quarter of an inch below a joint, splitting the stem in an upward direction to a point half an inch above the joint. The lower portion of the half stem should then be cut away just at the base of the joint. The shoot should now be bent upwards, thus opening the incision. In this position it should be lowered into the cavity scooped out and some of the sandy compost filled in. This will, of course, keep the incision open. The soil should then be pressed firm. Some advocate pegging down the layer, but if a finish is made with some of the ordinary garden soil this attention is quite unnecessary. On soils highly suitable for Carnation culture, a good plan is to layer several shoots round a plant and allow them to develop *in situ*, thus forming an imposing clump of plants. It should be noted that although the foregoing is the orthodox method of layering, Carnations root quite freely if a shield-shaped portion of the stem is cut out with a thin bladed knife a little below a joint.

Tulips which were lifted to make way for summer borders and were heeled in to ripen off should now be lifted and overhauled. The stronger bulbs should be cleaned and stored in a cool, dry place for planting in the autumn, while the weaker ones should be discarded.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Nierembergia frutescens, *N. filicaulis* and *N. gracilis* are all beautiful plants suitable for the cool greenhouse. They are of a slender shrubby habit and produce their lilac or bluish white flowers in wonderful profusion. They are all more or less half-hardy in light, dry soils and easily raised from seed or by means of cuttings. If seed is sown at this time good plants will be obtained which will flower next year. Plants that have just finished flowering should be partly cut back and stood in a warm greenhouse, when plenty of cuttings will soon be produced. If cuttings are secured during August, they root readily in a close case. When rooted they should be potted off singly into small pots and during winter should be kept fairly dry at the root and well up to the roof glass in a cool greenhouse. In their younger stages they should be pinched frequently to induce a bushy habit.

Calceolarias.—Seed of the large-flowered herbaceous section should now be sown in pans containing light rich soil. The pans should be watered some hours before sowing. The fine seed should be sown on the surface without any covering, and the seed-pans stood in a cool greenhouse and covered with a pane of glass, keeping them shaded until germination takes place. When large enough to handle the seedlings should be pricked off into pans or boxes containing light rich soil. When large enough they should be potted off singly into small pots. Calceolarias like cool and moist atmospheric conditions at all times. They are very subject to attack by green fly, which should be prevented by frequent light fumigations.

Chironia linoides is a very beautiful greenhouse plant which may be propagated by means of cuttings at this time. Cuttings root readily in a close case in a cool greenhouse. Plants from cuttings rooted now will make nice specimens in 48-sized pots for flowering towards the end of next summer.

Chironia baccifera is also a very desirable species, which may be increased by means of either seeds or cuttings. This species, in addition to its flowers, produces its red berry-like fruits very freely, which remain on the plants for a long time. All the Chironias are very subject to attack by the so-called begonia mite, which, however, may easily be prevented by the use of the sulphur vaporiser. They all succeed in an ordinary greenhouse, and require a compost of medium loam with the addition of a little peat or well decayed leaf-soil.

Ochna serrulata.—This handsome plant has been in cultivation for many years under the name of *O. multiflora*, and it produces its small yellow flowers very freely. They are, however, short lived. The plant's chief attraction, is its bright red calyx and fleshy receptacles, on which its black fruits about the size of Peas are placed. This plant is easily raised from seed or cuttings of half-ripened wood during the summer. In its younger stages it enjoys an intermediate temperature, but when in flower and fruit stands quite well in an ordinary greenhouse. It also makes a nice bush when planted out in a bed or border in the conservatory.

Cyclamens raised from seed sown last year, if not already moved, should now be put into their flowering pots. The compost should consist of a good medium loam, with the addition of a little leaf-soil; while old mortar rubble may be used in place of sand to keep the whole open and porous. They should be grown in low pits or in cold frames. The latter are the best, as the lights may be taken off in the evening so that the plants get the benefit of dews during the night. Cyclamens enjoy cool, moist conditions at all times. Cyclamen seed should be sown next month. In the immediate neighbourhood of London I find it an advantage to sow during July, as owing to lack of light they make little or no progress during the winter months. It is very essential that Cyclamen seed be fresh, or else germination is slow and uncertain.

Calceolaria violacea.—Plants propagated during the spring are now making nice plants, and should be potted on as they require it. This distinct Calceolaria may be successfully propagated at this time, and will make nice plants for next year. If planted out in a cold conservatory it makes a fine large specimen, as it is more or less hardy against a wall in the South and West. It is a good plant for an unheated house. This Calceolaria belongs to a section of the genus with open helmet-shaped flowers, there being only four species in this section, two native of South America and two from New Zealand, the only other species in cultivation being *C. Sinclarii* from New Zealand.

Royal Botanic Gardens, Kew. J. COULTS.

EDITOR'S TABLE

From Mr. C. H. Herbert of Hazelwood Nurseries, Acock's Green, Birmingham, came a sheaf of his new seedling Oriental Poppy *Salmon Queen*. This is a very large and shapely variety of rich salmon rose colouring. It combines brilliant colour effect for the border with perfection of form. The expanded blossoms reach round, across,

Penistemon heterophyllus is one of the most brilliant of a genus very rich in species and varieties of striking colours. It is a sub-shrubby Californian plant, growing to about 18 ins. in height, with slender stems and narrow, grey-green leaves which often assume a bronzy tint. The flowers begin to appear in early July, and these are tubular, about 1 in. in length and of a most vivid metallic blue "shot" with subtle tones of rosy pink and purple. A group of *P. heterophyllus* thus produces an effect of most dazzling splendour, and young plants (raised from cuttings struck in a cold frame) will all flower during their first year. In mild localities this attractive plant will often survive the winter and prove quite permanent, but it needs a well drained soil and plenty of sun. In some gardens *P. heterophyllus* appears to be attacked by a disease, probably fungoid, which suddenly destroys the plants when in their full summer beauty, but thorough drainage, full exposure and some lime in the soil will often avert such disasters.

A Record?—What is perhaps a record single consignment of farm and garden seeds has recently been dispatched by Messrs. Webb and Sons, Limited, of Stourbridge to their New Zealand agents, Messrs. Murray, Roberts and Co. of Wellington. Fifty-four large galvanised iron tanks were required for the seeds, and the aggregate gross weight was over 50 tons.

The Netherland and Indian - Netherland Horticultural Exhibition.—Although the closing of the list of exhibitors for the coming Netherland and Netherland Indian Horticultural Exhibition (to be held from September 14 to 23) will not take place before August 1, we are informed already that all branches of horticulture will be thoroughly well represented. Not only Dutch, but also English, Belgian, French and German growers have already applied for space. The greatest attraction of this Show, however, will be formed by the exhibits of the many horticultural associations, whose members have combined to stage their flowers in one great collection. This Show bids fair to be one of the most noteworthy of the Jubilee exhibitions of the Netherlands Horticultural Society.

Edinburgh's New City Gardener.—The Town Council of Edinburgh has appointed Mr. John T. Jeffrey, head-gardener to Sir Robert W. Buchanan-Jardine, Bt., Castle Milk, Lockerbie, to be City Gardener, the title applied by the Council to its superintendent of parks. Mr. Jeffrey is to be congratulated on his appointment out of eighty-four applicants, and the city has every assurance that in him they have appointed one who is fully qualified to perform the responsible and steadily increasing duties which devolve upon him. Mr. Jeffrey, who is thirty-nine years of age, is a son of the late Mr. James Jeffrey, gardener at St. Mary's Isle, Kirkcudbright, for a number of years until his death and, for a considerable time previously, gardener to the Earl of Harewood at Harewood Hall. In the latter place the new City Gardener of Edinburgh began his horticultural career under his father, and in due course, after gaining other experience, went to Eaton Hall, the seat of the Duke of Westminster,

where he was foreman over some of the most important departments. About thirteen years ago Mr. Jeffrey was appointed head-gardener to Sir Robert W. Buchanan-Jardine, Bt., at Castle Milk, Lockerbie, and during his appointment many improvements have been effected in the gardens and grounds under his charge there. Castle Milk is one of the largest and best kept Scottish gardens, and the experience gained there and in previous places has fully qualified Mr. Jeffrey for the important post to which he has now been appointed. It will be remembered that Mr. Jeffrey wrote one of the sections of "Gardening of the Week" for THE GARDEN some time ago. His elder brother, Mr. James Jeffrey, is head-gardener to Lord Lonsdale at Lowther Castle.

The Horticultural Club.—We have received the following from the Club's Hon. Secretary, Mr. Geo. F. Tinley, 5, Tavistock Street, Covent Garden, W.C.2: "During the past few years the Committee has been able to meet the expenses of the Club without calling on the members for their usual subscriptions of one guinea. As, however, the balance in hand which enabled this to be done is now exhausted, it was decided at the last general meeting again to ask the members for subscriptions. The sum fixed for the present year is half a guinea only. This should be sent to the Hon. Treasurer, Mr. Peter R. Barr, 11, King Street, Covent Garden, W.C.2. Members are also asked to induce any of their friends interested in horticulture to become members, as the Committee is most anxious to restore the Club to its former strength and importance. Periodical meetings during the autumn and winter will continue to be held in some suitable building, where a dinner will be provided at a moderate price, followed by music and a lecture on some gardening subject. The usual annual outing has been fixed for Wednesday, July 25, when a visit will be made to Windsor Castle, permission having been granted the Club to inspect the gardens and the State Apartments. The journey will be made by road and river. The price of the tickets (21s.) is inclusive of fares, luncheon and tea. The party will assemble on the Embankment outside Charing Cross District Railway Station at 10 a.m., reach Staines Railway Bridge at 11.20 a.m., depart by launch at 11.30 a.m., arrive at Windsor at 1.20 p.m., lunch at 1.30 p.m., inspect the Castle and Gardens, return to White Hart Hotel for tea at 5.30 p.m., and depart by chars-à-bancs at 6.30 p.m., reaching Charing Cross at 8.15 p.m. Application for tickets for members and friends (ladies included) should be sent early to the Hon. Secretary at the above address."

Answers to Correspondents

FRUIT GARDEN.

APPLE TREES ATTACKED (Miss S. and E. F. B.).—The Apple is attacked by the apple scab fungus. Next winter prune out all the diseased shoots and spurs, especially those showing cracks or dead areas in the bark, and spray the tree with Bordeaux mixture just before the buds burst and again after the petals fall.

MISCELLANEOUS.

PRIMULA POISONING (R. McL.).—*Primula Eureka* is doubtless the cause of the trouble. It is—if not, as is probable, pure *Primula obconica*—a form with a great deal of *P. obconica* blood in it.

THE PRIMULAS OF EUROPE

With Botanical Classification, Descriptions, and
Cultural Instructions

By **JOHN MACWATT, M.B.**

Crown 8vo., Cloth, 12/6 net; Postage 9d. extra.

The aim of the author has been to produce a handbook that will assist in the identification of those species of the genus *Primula* which are native to the European continent, and at the same time furnish practical guidance to the cultivation of such of them as have been introduced to our gardens where conditions differ so widely from those prevailing in their natural habitats.

Dr. MACWATT is an acknowledged authority on *Primulas*, and his book presents in a concise and interesting manner the results of many years of close personal observation and experience.

NICOTINE! NICOTINE! NICOTINE!

No Compound, poisonous or non-poisonous, is as effective or as safe as English-made Nicotine for destroying all sucking insects infesting vegetation. It cannot be bought in a more convenient form for spraying or syringing than as—

CAMPBELL'S NICO SOAP (Nicotine Soap). The best Potash Soft Soap plus 7½ per cent. Nicotine. A teaspoonful will make one gallon of strong spray fluid. Prices:—½ lb., 2/-; 1 lb., 4/-; 10 lb., 32/-.

CAMPBELL'S ENGLISH NICOTINE, 95-98 per cent. This is offered to large users or others preferring to make up their own fumigating and spraying compounds. Prices on application.

CAMPBELL'S NICOTINE VAPORISING COMPOUND. Nicotine content, 50 per cent. Prices:—10z., 1/6; 4oz., 3/9; 8oz., 7/6; ½ pint, 9/-; 1 pint, 17/6; ½ gallon, 61/-.

CAMPBELL'S NICOTINE FUMIGATING ROLLS, very simple and effective. In four sizes for 500, 1,000, 2,000 and 3,000 cubic feet. Prices:—7d., 10d., 1/6 and 2/- each.

CAMPBELL'S PATENT SULPHUR VAPORISER. The best method of exterminating Mildew from plants in greenhouses. In two sizes, for 5,000 and 10,000 cubic feet. Prices:—18/- and 20/- each.

Obtainable from Seedsman, or, in case of difficulty, direct from the Manufacturer—

[JULY 28, 1923.]

THE EVOLUTION OF THE MODERN GLADIOLUS

CONSIDERING the marked limitations of the numerous species of Gladioli as regards colour and form, it is at once instructive and very wonderful to contemplate the exceptional strides made by man in producing the gorgeous flowers seen in the modern Gladiolus. The European wildings are mostly weedy and useless specimens, byzantinus alone being worth cultivation, and that solely because of its purple colour and near approach to hardness in British gardens. That wonderland of Irids, South Africa, has, naturally enough, contributed lavishly to the making of the Gladiolus of to-day, the principal species employed being psittacinus, cardinalis, Saundersii, oppositiflorus, cruentus, dracocephalus, purpureo-auratus, Quartinianus, cuspidatus and tristis. The first great step towards the evolution of a really valuable garden plant was made in 1837 by Bedinghans of Arenberg when he first bloomed the seedlings of *G. psittacinus* × *cardinalis* or *oppositiflorus*, the certainty of the second parent never having been clearly established. The famous florist Louis van Houtte of Ghent seeing these flowers and sensing their importance immediately purchased the stock and named them *Gladiolus gandavensis*. Later on, Souchet at Malmaison carried the work on these lines considerably further. The *gandavensis* race were probably taken up by Max Leichtlin in Germany and Lemoine in France, the former crossing them with *Saundersii* to form the *Childsii* group—named by John Lewis Childs, who had taken over the Baden-Baden seedlings of Leichtlin from an American, Halloch of Long Island, their original purchaser. Meanwhile Lemoine of Nancy was working on *gandavensis* × *purpureo-auratus*, the latter a greenish yellow small-flowered species having a conspicuous maroon blotch. This produced the now well known *Lemoinei* race, noted for their brilliantly blotched flowers, although there is some probability that the species *Papilio*, with small purple-red flowers, also entered into the genesis of this group. The *Lemoinei* hybrids, having proved their worth, the same

raiser worked these on to *Saundersii*, a scarlet species with prettily spotted throat. The resulting seedlings gave many large wide-petalled flowers retaining the vivid colours of *Lemoinei*, and this family was called *nanceianus* in honour of the home town of the raiser, and numerous Gladioli of very high quality are embraced in that group. Lemoine also employed the species *dracocephalus* and others of lesser note, but nothing much seems to have come from these efforts. Coming down

to more modern times, Dr. Van Fleet in America made quite a notable step forward by producing *Princeps*, the product of the species *cruentus* crossed with one of the *Childsii* seedlings. This was hailed as a great flower in its day, and is still grown in many gardens for its great size and fine colour, but only two or three flowers are open at once, and its habit is dwarf, so that it is now outclassed entirely by newer varieties. In recent years Messrs. Kelway of Langport, father and son, have worked untiringly to improve these large-flowered Gladioli, and have produced hundreds of hybrids of glorious colour and habit well known to habitués of Vincent Square.

A surprising and altogether revolutionary development occurred when the species *primulinus* was discovered during Sir Francis Fox's engineering work on the Zambesi bridge in the opening years of the present century. For the first time a bright clear yellow was available for hybridisers, and this, combined with a native grace of form, both in spike and flower, has already entirely altered our conceptions of value in the garden or decorative qualities of the Gladiolus. So important, indeed, did the hybrids of *G. primulinus* become that during the last few years the whole race of summer and autumn flowering Gladioli have been divided into two sections only, viz., large-flowered and *primulinus* hybrids. The individual characteristics of the *gandavensis*, *Childsii*, *nanceianus* and *Lemoinei* have become so amalgamated and blended by intercrossing that it is impossible, and quite unnecessary, to attempt to place the modern large-flowered hybrids in their generic sections. As was inevitable, the *primulinus* hybrids also are threatened with absorption unless strong measures are taken to keep them in a class by themselves, and it looks as if a fresh development is now pending along the lines of classification.

In our own gardens at Crawley Down we have many thousands of hybrids of the most glorious colours—imaginable, the flowers of which are too large to be classed with the true *primulinus* race, yet the bloom spikes retain much of the grace and

GLADIOLUS ODIN. A GANDAVENSIS VARIETY

With brilliant salmon-flushed flowers, and each lower segment has a definite crimson bar on scarlet ground. Award of Merit, 1921.

texture of its perianth are distinct points in its favour. Somehow though it has not that undefinable look of distinction which impressed me so much last year in Silver Plane. Perhaps above everything else its scent is its most distinguishing feature. Unless it has Jonquil blood in its veins, it surpasses all I have ever come across.

A real surprise packet came from Australia one March morning containing six ideal bulbs of a Jonquil hybrid Gertrude Nethercote. They were planted early in April and are now in flower (July 10), as I was able to demonstrate by having one in my buttonhole at the R.H.S. meeting in

London on that date. It is a very good variety and is distinguished by the way the long trumpet (?) widens out gradually towards the brim. Each stem has a single flower. Two flowers would be clumsy, as each one has a diameter of from 3 ins. to 3½ ins.

Roses in January and ice in June were once spoken of as utter impossibilities! Daffodils in July surely go one better. How guests would stare if on one of the evenings of the Oxford and Cambridge match they were to find the dinner-table "done" with Daffodils. It is quite possible. J. J.

ABOUT ENGLISH IRISES

ENGLISH Irises have been inhabitants of our gardens longer than any other members of the Iris family. I have read that the date of their arrival from Spain was 1571, and that before long they had become so numerous in the west part of England that they were to be found "in all Countrey folkes Gardens thereabouts." In fact, Lobel stated that they were to be found wild, but Parkinson (1629) doubted this very much, and in all likelihood it was but a stretch of the imagination. In those distant days Bristol was a port of the first magnitude, and would be the great distributing centre for commerce from Spain and Portugal. Repeated importations by travellers who were "delighted with the beauty of the flower," and their quick increase which resulted in their being "imparted to many" soon made the "Blew English bulbous Flower de luce" extremely common, so much so that they became known as English in contradistinction to the smaller-flowered and narrower-leaved Flower de luce which some quarter of a century later was also brought over from Spain, and which was called the "Narrow-leaved bulbous Flower de luce." These are what we now call "Spanish Irises," and it is of interest to note that as long ago as 1676 (2nd Edition, "Rea's Flora, Ceres and Pomona") between fifty and sixty named varieties were offered for sale by Morin, the famous flower dealer of Paris. Just as is the case to-day, the flower books of the seventeenth century record the fact that it was the same when they were written. English varieties are not as numerous as Spanish. Again, we are all of us painfully aware of the unfortunate tendency of all self English Irises to become spotted or striped. Is this as "old as the hills"? I ask the question because Parkinson on page 173 of the "Paradisus" describes (No. 3) a "purple stript bulbous Flower de luce." It looks very much as if it were so. The cause of this sudden conversion of self coloured into striped or spotted flowers is by no means confined to this family. The most famous and best known example is the Tulip. No theory that is entirely satisfactory has so far been evolved to account for it.

The latest out is that the change is caused by an infectious disease to which the name "mosaic disease" has been given, but what it is or how it works I fear I do not know. If my memory serves me, this striping among English Irises has become more common within the last dozen years. In the two collections of over fifty varieties which have flowered here (Whitewell) this summer, there is not one that has not all or some of its flowers striped. It was not always like this. I used to grow a deep purple and a dark blue which never were anything but selfs, and a beautiful pinky mauve seedling of my own named Attraction

never shewed the least spot or blotch until last year when, after a long interregnum, I bought once again a few varieties just to see "what was

ENGLISH IRISES (I. XIPHIOIDES).

doing" in English Irises. Attraction was planted in 1921 side by side with the others in one long bed. Up to that time for at least seven years it had been the only English Iris variety in the garden. Could the infection pass from one plant to another during their period of growth or while they were in bloom? Attraction had a few broken flowers in 1922. I have been told that if I had never got any new bulbs and if I had been content to stick to my one and only, all would have been well and my seedling would never have had a stain upon its character. Can anyone say if this might have been so? Has anyone at the present time pure self varieties with the exception perhaps of one or two whites?

I think the English Iris has a sort of grievance against our English bulb dealers. They are not encouraged. I have looked in vain through the lists of several of our best-known firms and only in two—those of Barr and Sons of Covent Garden and Wallace of Tunbridge Wells—have I found anything like a decent-sized collection. One might imagine from this that there are only two or three really distinct varieties. But this is not

the case. Last autumn I planted some bulbs of every variety in Messrs. Barr and Sons' collection and some of every variety in that of van Tubergen of Haarlem. The varieties I am about to name as being good according to my judgment and taste are taken from these. I mention this because the nomenclature of English Irises seems to be a pretty good mix up, so one must be cautious when buying.

Taking blue shades first, undoubtedly the finest of all is Princess Juliana (T.). It has enormous falls of a deep blue with a bold white blotch in the centre of each and large wide standards of the same shade. If only that second flower would not try to assert itself before the first is fully developed! It does throw things out of gear, and thereby the symmetry of the falls and standards is disarranged. This seems rather more conspicuous in Princess Juliana on account of its size than in any other, but every variety suffers to some extent in the same way. My head-gardener often says, "Ah, if only they had

but one flower!" He is right in one way, but as the second always opens whether the stem is growing or cut, I cannot quite bring myself to say "I agree." The richest shade of all was found in Prince of Wales (B.). A royal purple blue is how I describe it in my notes. My third favourite is King of the Blues (T.). It is a beautiful soft shade. The rosy or reddish purples are a great feature of the family and make a telling appeal to visitors. Some call the colour "petunia." A good many of them clamour for recognition, but after much consideration I have picked out these three: First, Rosalie (B.), so very clean-looking and bright; second, La Marquise (T.), rich and dark; and third, Dandy. In whites Mer de Glace (T.) is an improvement, I think, on the very old but still very good Mont Blanc.

What to say about the lavenders and pale pinky mauves I do not know. In these more than in any other shades the striping and streaking is often an eyesore, but when there is not much of it some are quite pretty. Perhaps a fair selection would be Lusinda (T.), Tantalus (T. and B.),

Perle des Indes (F.) and Cattleya (B.) but there is something about the counting for taste. One day a charming friend came along and spotted the carnation flower of Lamartine (L.) as the one he liked best out of all the varieties in the two collections. "Ugh!" was the general comment on it. Now we come to a type which is difficult to describe. It seems to have affinities to the veined Renchocylus and the Japanese type. Somehow

the coloring looks as if it had been printed on the tails from a transfer in the same way that certain kinds of old china used to be ornamented. Try these next year! Almona (B.), Miss Answorth (B.) and Tipador (F.). This last is fine in a mass when it has "got going." One word in conclusion: English lilies like stiff soil. Both Dutch and Spanish like it light. *Yerb. sap.*

JOSEPH JACOB.

THE LATER BROOMS

THE late-flowering form of the Common Broom (*Cytisus scoparius*) must not only be considered one of the most valuable members of its family by reason of the fact that, commencing after the type has gone off, it carries on the flowering season to August, but it has some other notable attributes. Here, at any rate, the Late Broom attains to nearly double the height of the wild species, and this extraordinary vigour is emphasised also in the unusual leafiness of the branches, in the size of the blossoms, their fine depth of colour and amazing prodigality. Some of our specimens (all grown from seed, usually selected annually from the last to flower) have made a bold, upright stem, thick as a man's arm at the base, and attained the height of 8 ft. and more. Not a few of the shrubs then assume a dense, mop-headed form from which the long, twiggly branches radiate and droop with their heavy burden of deep yellow flowers. There is little or none of that pale grey green hue in the foliage of the Late Brooms which one usually associates with the more whippy wild plants, and the comparatively heavy, dark green of the former doubtless helps to give both their flower and form that impression of

scented, come to permeate the silvery gloss of the bushes with a woof of gold. Though a Mediterranean species, *G. virgata* has never been injured by frost here. It may be readily grown from seed, and the young plants grow away with extraordinary rapidity.

Another July bloomer which is not less admirable for hot, dry soils than the foregoing is *G. atnensis*, a Sicilian, which is also quite hardy with us, as it is at Kew, where it may be seen growing some 14 ft. in height. But this Broom possesses to an exaggerated degree the habit (not uncommon in the genus) of growing leggy with age, so that young plants should be kept in reserve for replacing overgrown specimens, more especially in smaller gardens. Even these, however, will, in the case of *G. atnensis*, often assume somewhat gaunt and ungainly shapes, and for that reason we prefer to grow the species where the lanky lower portions of the plants will be partly hidden by some lowlier shrubs. The branches of *G. atnensis* are thin, cord-like and leafless, and they droop in a by no means inelegant shower of pea green from the top of the main stem. The blossoms, which are yellow and fragrant, appear on the tender young growths of the current year, and these latter

continues well into autumn. Here, again, young bushes (cut hard back in spring) are much superior to old ones, and the form known as *C. n. Carlieri* is even better than the type. *C. nigricans* and its varieties may be grouped in any sunny spot where the soil is poor, and there the bushes will not fail to yield a prolific crop of bright yellow flowers borne on tapering, upright spikes some 8 ins. or more in length.

Genista radiata is an interesting little shrub for associating with Heaths or planting in open woodland spaces, and then there is the tinctoria clan, of which the earliest and longest bloomer is *G. tinctoria* var. *mantica* (*Carniola mantica*). This has the hard, glossy green leafage which distinguishes the family, and the orange-yellow spikes of blossom are produced in lavish profusion throughout midsummer and again in autumn. The double-flowered, prostrate form of *G. tinctoria* is an excellent little plant, making a densely green mat of foliage which breaks into a blaze of yellow flowers at this season no matter how hot and dry the soil may be. Then there is the best tall form of the species known as *G. t. elatior*, for whose spires of bloom one is thankful when most things are passing over even though the yellow is a trifle tarnished.

G. capitatus is a July-autumn bloomer which might be more often grown, and the merits of *G. cinerea* also deserve wider popularity. Such remarks, indeed, might well be applied to many other worthy members of this great and fascinating family, and the reason why a race of such easy culture and possessing such superlative attributes is not more generally appreciated is a problem.

Even the splendid old *Spartium junceum*, which has been known to us for close on four hundred years, has not been accorded one-half the recognition it so fully deserves. A free and hearty grower in almost any soil, in sun or shade (even under deciduous trees), one that will maintain a prodigious crop of large, rich yellow, sweet-scented blossoms for six months of the year, and these on long, straight stems which make them admirable for cutting, is a shrub of no ordinary merit. One may add to these good qualities the fact that the Spanish Broom can be readily increased by seed sown in the open and that established plants never need any attention whatsoever.

It may be that the popular myth regarding the alleged difficulty of transplanting Brooms may be responsible for the shyness with which so many amateurs appear to regard these shrubs. If, however, Brooms are put out before they have commenced to flower, there is no more reason to expect losses than there is in planting Privet. Even older specimens of most kinds may be moved with every hope of success if one or two of the leading branches are cut back to half their length at planting-time.

Though the soil allocated to Brooms in this garden is a poor, sharply drained shale, often so stony that an iron bar has to be used to penetrate it, no preparation whatsoever is made for these shrubs. They are set out, usually in autumn, direct from the seed-bed (or the frames in the case of those which have to be raised from cuttings) and left alone. No pests, other than mice, which may nip them back while they are still young, ever attack them; they seem to be immune from disease, and never need such attentions as watering, mulching, staking and the rest, while very few ever need pruning. Yet with all these obliging and delightful qualities Brooms are only grown in a few gardens as they might be grown in many. Albeit, when they are seen in good form what shrubs are more generally admired?

NORTH WALLS.

AMONG THE MOST USEFUL OF LATE-FLOWERING BROOMS, GENISTA CINEREA.

sumptuousness and well being which is so distinctive a feature of these splendid plants.

In striking contrast to the above is the shy, grey-green of *Genista virgata*, whose fine-leaved foliage glimmers with a livery silkiness at each breath of wind. Whether grown singly or grouped, this is an attractive species at all seasons, but it is never so beautiful as it is in July, when the multitudes of little yellow flowers, deliciously

also bear a few delicate leaflets, which disappear with the ripening of the shoots. This species may also be raised from seed, though the latter does not germinate so freely as that of most. The white *G. monosperma* appears to be closely allied to the last mentioned, but it is a good deal more tender.

C. nigricans is an indispensable species, since it comes into flower towards the end of July and

HERBACEOUS PLANTS OF A WOODLAND GARDEN

FEW plants are more admirably suited for woodland planting than the Willow Gentians, *G. asclepiadea*. They will do quite happily under trees where the shade is not too dense and, though by no means fastidious, enjoy a deep, cool vegetable soil. There are many forms of this fine Gentian, these varying in height from 1ft. to 4ft. and bearing large, tubular flowers from a dull slaty blue to a beautiful sapphire, while others will range between a full azure and a rich violet blue. Some of these are, I believe, sent out under specific names, but they are all of the same clan, most of them make a bold sheaf of elegant, arching growths and along the upper half of each stem the flowers appear at the axils of the opposite pairs of leaves in July and August. Though not the tallest, *G. a. Perry's Blue*, a clear azure, is one of the best of this set, and the pure white variety is irresistibly lovely and distinct.

Distinguished by its broad and crisp bronzy leaves, which look as if they had come direct from a milliner's window, is *Deinanthe cœrulea*, a distant relation of the Saxifrages, which will also do well where the Willow Gentian prospers. This uncommon plant grows to about 6ins. in height and makes amends for the parched and crinkly appearance of its bristly leaves by producing in early August large waxen blossoms which suggest in their chaste and drooping loveliness those of some magnified *Pyrola*. These exquisite flowers, which are all that the dismal leafage is not, are of that most delicate and rare shade of palest violet-blue which one associates with sunlit mist among the hills of autumn. This weirdly beautiful creature appears to enjoy considerable but not heavy shade, and it revels in a naturally moist bed containing peat or leaf-mould.

Boykinia aconitifolia is yet another woodlander of similar wants, and it also is allied to Saxifraga. This is not such a striking plant as the last mentioned, but its bold and silky leaves with their neatly indented lobes and fresh, soft green are distinctly attractive. These will soon cover a considerable space, the plant running about like *Geranium grandiflorum*, and during the later summer this foliage is surmounted to the height of some 18ins. or more by stately flower-stems which bear ample heads of pretty milk white blossoms.

The much smaller *Tanackæa radicans*, though not strictly herbaceous, also delights in these sun-screened, moist, but well drained corners, and it is a cheerful little plant for the edge of a woodland path or to associate with other lowly things. It seems to enjoy the exploration of stony crevices with its wiry runners, and such places it will soon embroider with wreaths of leathery dark green leaves above which in summer rise the 6in. inflorescences which might be taken for the silvery panicles of some Tiny Tim of the great *Aruncus* breed.

From *Tanackæa* of Japan it is but a short step to *Astilbe simplicifolia* of the same flowery land, and no one who owns a garden of any sort which affords one of those cool corners I have referred to should omit this treasure. Nor is it so fastidious in regard to dampness as many of its race. We have it associated with the little *Spiræa decumbens*, now a most cheerful sight with its foaming inflorescences, with *Spiræa bullata*, whose gloomy green is breaking into an eruption of ruby buds, and with the no less delightful *Spiræa digitata nana*, a miniature *palmata*, and the most precious jewel of its distinguished family. *A. simplicifolia* is

growing among this select little company in very ordinary soil which is anything but moist, although it is never parched; and above its keenly notched and finely pointed leaves, which do not rise more than a few inches, ascend in full summer those airy plumes of tiny white or bluish flowers which are like fairy fountains of iridescent spray.

Nearer the waterside *S. Aruncus* led the way early in the month for the rest of its handsome tribe, among which latter *S. palmata* in both the raspberry pink and pure white must always be given a foremost place. *SS. lobata* and *venusta*, which appear to be one and the same thing, are American Meadow Sweets also of the highest merit, their foamy crests ranging in colour from creamy white and bluish to the full-toned raspberry pink of *palmata*. Then there is *Spiræa Kneiffi*, a dwarfed form of the Goat's-beard *Aruncus*, with its leaves shredded into mere skeletons of green, and the giant of the race, *S. kamschatica (gigantea)*, which is an admirable plant when it has lots of room, moisture and manure, plus a birth certificate testifying that it is of a really good form and not some degenerate seedling.

Astilbe Davidii is also here, shooting up among the later days long fuzzy spires of puce magenta blossoms which may without risk of offending anybody be associated with the taller (5ft.) and more elegant *A. grandis*, whose ropes of creamy white bend over a foliage of singular grace and beauty. Then there are some of the *S. japonica* hybrids, but as these are too much inclined to deteriorate with us without considerable attention, they are unsuitable for woodland planting in a garden where the plants have pretty much to fend for themselves in a natural manner. There is, however, yet one more plant that must claim admission to this company, and that is *Gillenia trifoliata*. This is not a showy plant, but there is something very arresting about its 2ft. sheaf of dark green foliage and gracefully drooping three-lobed leaves. Then it is a late flowerer, the bright little showers of white or rosy white stars appearing towards the end of the present month and continuing until the latest of the *Spiræas* have been stained with the rust of their passing. *G. trifoliata* does very nicely in any place where the above-mentioned plants thrive, but it should be set a little apart from such pushful fellows as the more stalwart *Aruncuses*.

In rather drier ground, but still in partial shade, *Lysimachia clethroides* is now an effective plant especially in the mass, its white spikes curiously bent at an obtuse angle over the tall, leafy stems. This, however, is inclined to trespass, and should be placed well away from choicer things and in company with such other handsome offenders as the stately *Epilobium hirsutum* (the variety with white flowers), *Lysimachia punctata*, *Centranthus*, *Rodgersias* and others. Of the common *Rodgersias*, *R. tabularis* is, I think, the most attractive,

and for a really moist place there are few more noble plants of moderate dimensions in this character than *Saxifrage peltata*.

All the Borages and Alkanets are useful for woodland and late bloomers, the little trailing *Borago laxiflora* with its dainty bells of rosy-tinted azure being especially charming when naturalised among native herbage, and one that will maintain a succession of bloom from May to December.

THE BUTTERFLIES' FAVOURITE—*BUPHTHALMUM SPECIOSUM*, IN WOODLAND.

The Welsh Poppy, seductively fascinating as it is, would be kept within bounds along with those other malefactors on parole mentioned above, if it were humanly possible to do so. But nothing can stay the "peaceful penetration" of its abounding legions. Yet, if *Meconopsis cambrica* were difficult to establish, if it were only biennial, how we should prize its soft lettuce green foliage and lovely flowers, of which the lively daffodil yellow blends so well with the prevailing green of woodland floor and waterside! Curiously enough, the orange form, which is a really delightful thing, is a comparatively feeble coloniser even in places where the type abounds like the wicked.

Most of the *Mulleins* are first-rate plants for fairly open woodland, but a good many of these (like the choicer of the *Meconopsis* tribe) are biennial, and so demand more attention than some of us can afford for plantings of this nature. The most permanent here, and one which we should not like ever to be without, is *Verbascum nigrum*, whose 3ft. spires of yellow or white, if not remarkably distinguished, seem to harmonise admirably with other sylvan plants. Then they hold themselves up—and a plant that cannot do that has no place in the wild or semi-wild garden. Some

the *F. of Martini*, such as *Mr. Willmott*, have also proved fairly permanent and independent enough for woodland culture, and no less can be added to the noble *V. philomoides*, which is certainly desirable.

The *Funarias* are invaluable for shady places, and some of them may be counted among the best of our later herbaceous plants for the purpose in view. Provided the root-hold is deep enough, these handsome plants do not insist upon a really moist position, but few things more thoroughly enjoy good living or more generously repay one for affording them a liberal hospitality. *F. Sieboldii* is a well tried species, and the somewhat smaller *F. Fortunei*, whose leaves are still more glaucous than the preceding, is also first rate. Both produce fine spikes of pretty tubular flowers

in colour lavender or pale violet during the later summer.

Polygonatum (Solomon's Seal) is an indispensable woodland plant, and one that will often thrive where few other things could exist. In addition to the common species there are one or two others of this genus that are well worth a trial. The great tribe of Knotweeds (*Polygonum*) also affords us one or two good herbaceous kinds for our purpose here. Of these *P. alpinum* makes a pleasing clump some 3 ft. high of fresh green foliage terminating in flossy panicles of white. This species does not appear to be such a rampant spreader as so many of the Knotweeds are, but the discreet will not handle any of them without due caution. The rosy pink *P. affine* is a charming orn. carpeter for a fairly moist place, and the

closely allied and taller *Brunonis* is equally pretty. As, however, I have not grown either of these *Hindlayans* I know not what evil may lurk behind their blushing smiles.

These rambling notes cannot be concluded without a good word for our old friend *Bupthalmum* (*Telekia*) *speciosum*, whose splendid heart-shaped, sappy leaves never flinch in the most droughty August weather, and whose noble orange yellow suns seem to glow with the very essence of autumn's merry hues. A few clumps of this proud old Ox-eye

to give "*Bupthalmum*" in presentable English—standing in some sun-filled corner with all the handsomest butterflies sipping its "drowsy swarms" and basking in its blazing rays is a goodly thing to behold and one that few of us need forgo.

A. F. J.

THE NATIONAL ROSE SOCIETY'S PROVINCIAL SHOW

THIS Show was held at Robert's Park, Saltaire, on July 10 and 11 under ideal conditions. The heavy thunderstorm during the preceding day had cooled the air and, consequently, the flowers remained good throughout the two days. The Roses staged were of a very high standard and, although some of the classes were not well filled, the competition was very keen. The groups of Roses were well represented, and some fine examples of artistic arrangement were to be seen.

In the nurserymen's section, Messrs. Prior and Son of Colchester were first with lovely examples of *Lady Barham*, Mrs. George Marriott, Mrs. A. Carnegie, H. V. Machin, George Dickson and

L. Godfrey Brown. Messrs. F. Cant and Co. of Colchester were a close second; Mr. W. Singer of Newcastle, Co. Down, third; and Mr. Hugh Dickson of Belfast, fourth.

In the class for twenty-four blooms, distinct, Messrs. Prior and Son were first with a very even set of blooms; Mr. George Prince of Oxford second, with somewhat smaller blooms; and Mr. G. Burch, Peterborough, third.

In the class for twelve blooms, *Tea or Noisette*, Mr. George Prince was an easy first with magnificent examples of *Dr. Campbell Hall* (silver medal), Mrs. Mawley, *Golden Gate*, W. R. Smith and *Muriel Wilson*. Mr. Elisha J. Hicks of Hurst was second.

For twelve blooms of new Roses Mr. G. Prince was first with magnificent examples of *Mabel Morse*, *Diadem*, *Muriel Wilson* and Mrs. Lamplough. Messrs. D. Prior and Son were second, and included *Red Star*, *Lord Charlemont* and Mrs. Hy. Bowles. Mr. Elisha J. Hicks was third.

For a basket of cut Roses (Class 5) Mr. Hugh Dickson was first; Mr. Elisha J. Hicks, second; and Mr. G. Burch, third.

In the class for three baskets competition was very keen, and Messrs. Bees gained first honours with lovely examples of *Venus*, a magnificent Rose of their own raising. Mr. Elisha J. Hicks was second and Mr. Hugh Dickson third. A fourth prize was awarded in this class to Mr. George Prince.

ROSE FRID J. HARRISON, A NEW HYBRID TEA WHICH WAS AWARDED A GOLD MEDAL.

ROSE JOAN HOWARTH, A FLESH PINK HYBRID TEA. (CERTIFICATE OF MERIT.)

In the class for twenty-four distinct varieties Mr. G. Mattock of Oxford was first and Messrs. Frank Cant and Co., second.

In Class 8, twelve distinct varieties, Mr. Elisha J. Hicks was first with an even lot of clean fresh blooms; Messrs. Chaplin Brothers, second; and Mr. G. Burch, third.

In Class 9, one basket of cut Roses, Mr. Hugh Dickson was first; Messrs. Alex. Dickson and Son, second; and Messrs. Bees, Limited, third.

In Class 9, for a representative group of Roses, Messrs. Alex. Dickson and Son won first honours with a magnificent group which contained striking examples of Sunstar and Betty Uprichard. Messrs. Allen and Son, Norwich, were second.

Class 10 was for another representative group of Roses, and here the competition was very keen as the winner would hold the Saltaire Cup, valued at £50. Mr. George Priace of Oxford was first with a very fine group that contained some good examples of Souv. de Claudius Pernet, Mrs. Lamplough and Mrs. Foley Hobbs. The exhibit was perhaps a little crowded, but the quality of the blooms was faultless. Messrs. Chaplin Brothers of Waltham Cross were a very close second, and Mr. Elisha J. Hicks of Hurst was third.

The open artistic class for a bowl of Roses was won by Mr. G. Burch.

The amateur section was not as well represented as one would have wished, the exhibits being few and below the usual standard.

The Jubilee Trophy was won by Mrs. Balfour of Oxford. The same lady was first for the best twelve blooms open only to growers of less than 1,000 blooms.

In the classes for Roses in baskets Mrs. Balfour, Mr. Marriott and Mr. Bambridge were the successful exhibitors.

For a representative group of Roses Mr. Marriott of Carlton was an easy first with a fine group neatly arranged in bamboo stands. Mr. F. A. George of Worcester was second.

The table, bowl and vase classes were won by Mrs. Courtney Page of Enfield.

NEW ROSES.

No fewer than thirty-six new varieties of new Roses were staged, and two gold medals were awarded.

Allen Chandler (H.T.).—A strong-growing, semi-single Rose of distinctive merit. The blooms—scarlet in colour—large and sweetly scented and carried in clusters of three or four. A good pillar Rose and said to be perpetual flowering this should prove an acquisition. Gold medal. Shewn by Mr. George Prince.

Fred J. Harrison (H.T.).—A free and branching Rose suitable for garden purposes. Colour scarlet cerise sweetly scented. The blooms open rather thin. Shapely in the bud, not unlike Covent Garden. Gold medal. Shewn by Messrs. Alex. Dickson and Son.

Joan Howarth (H.T.).—A pretty flesh pink flower deepening at the base of the petals. Of fine upright growth, this variety is sweetly scented and very free—altogether a delightful garden Rose which keeps its colour and shape well. Certificate of merit. Shewn by Messrs. Bees, Limited.

Richard E. West (H.T.).—The pale lemon yellow petals are large and somewhat loose. The plant is free-flowering and the growth mildew proof. A fragrant garden variety. Certificate of merit. Shewn by Messrs. Alex. Dickson and Sons.

Betty Hulston (H.T.).—A vigorous, free-flowering, fragrant Rose, pale golden yellow in colour and somewhat after the style of Marquis de Siney. Purely a garden variety. Certificate of merit. Shewn by Messrs. Alex. Dickson and Sons.

MRS. COURTNEY PAGE'S PRIZE BOWL OF ROSES.

Annie Ireland (H.T.).—An enormous Druschki-like bloom of pale cream colouring. It has a high pointed centre and is faintly scented. An exhibition Rose. Certificate of merit. Shewn by Messrs. Alex. Dickson and Sons.

Fragrance (H.T.).—A scarlet crimson sweetly scented Rose with high pointed centre. Might be

described as an improved Laurent Carle. Certificate of merit. Shewn by Messrs. Chaplin Brothers.

Mrs. E. J. Hudson (H.T.).—A large Testout-like bloom with good depth of petal. The flowers are of good shape; indeed, it might easily be mistaken for Caroline Testout. It is faintly scented. Certificate of merit. Shewn by Mr. G. Lilly.

SEED SAVING

SEED-SAVING is to some people, myself, for instance, what money is to the miser, an end in itself, for I find myself saving seed which I not merely do not sow, but which I do not mean to sow. Sometimes it is the seed-capsule that is absorbingly curious. Sometimes the seed itself has the beauty of a jewel. Columbine seed, for instance; its jetty sheen and saltatory motion are a little suggestive, perhaps of the *Pulex irritans*, but, rightly considered, are none the less beautiful for that. Of the various seed apparatus known to me, for sheer fascination commend me to that of the Poppy. One never tires of wondering at the architecture of the capsule, with its clere-storey windows and its interior septa; and then, when you invert the ripe capsule on a sheet of foolscap, the patter of the seed-pearl on the paper is music. However, it is not with Poppy seed as an end in itself that I am concerned at present, but with the seed as a means to having finer Poppies next year than you have this.

Once secure a pinch of good seed and for a season or two you may allow your Shirley Poppies to sow themselves, with a fair assurance that, though among the seedlings there will be a fairly large proportion of mere weeds, there will also be for a year or two a considerable number of tolerably good blooms; with, possibly, here and there a flower that is better than good. But each year

will see the Poppies, as a whole, less choice than they were the year before. Reds and crude pinks will gradually supersede the more delicate shades, until at last the Shirley plot differs little from a patch of unregenerate Corn Poppy, which at its worst is of course still a pretty flower, though not a Shirley. Anyone who desires to keep his flowers up to the mark cannot hope to do this by any such happy-go-lucky method or lack of method. There are only two ways of securing seed that is really worth while: of which the papaverist must choose one, if he does not try both. Seed may be procured each year from a reliable dealer, an easy and pretty safe course to follow; and therefore, probably, most amateurs follow it. Or one may save one's own seed by a process of careful selection, which, from first to last, no doubt involves a good deal of labour, though we have excellent authority for the comforting assurance that "the labour we delight in physics pain." To my thinking flowers grown from seed of one's own selection are infinitely more interesting to the grower than those obtained from seed, however good, that comes from an outside source. In saving seed which it is of vital importance to have of the first quality—saving, for instance, for commercial purposes, or to fix a strain of exceptional value—one would no doubt proceed on the rigid lines which, I understand, the late Rev. W. Wilks set himself when he created the strain of Poppies

which subsequently took its name from his vicarage. In this drastic process of selection, which for my own purposes I do not think it necessary to follow, the main thing is to eliminate every undesirable specimen as soon as it shews its quality. To do this with such a flower as the Poppy, which opens at break of day, the grower would have to be up with the lark, or, to speak by the card, with the humble-bee, an earlier riser, I fancy, than the lark. (When I say "humble-bee" it is only because the hive-bee is, in my garden, as good as extinct.) Rise as early as you will in Poppy-time—before even the first flower has burst its sheath—and, as likely as not, you will find half a dozen young humble-bees there before you, hovering over the half-open cup, eager to pounce on among the floury anthers the moment the petals shake themselves apart. And a pretty dust the creatures raise when they tumble in this way into the flower, as if the fertilising of a Poppy capsule were a prime object of their existence; as possibly it is, in which case it is pleasant to think how thoroughly well they manage what they are there to do, for I defy any Poppy-head to remain sterile when once a hasty young humble-bee has floundered in among its stamens. Unless, therefore, one is up and at work before the sun, there is little use in attempting to eliminate the undesirables among one's Shirley Poppies, for, ten to one, the bees have been before you. Unfortunately (or fortunately, just as you regard it) on each flower it visits the bee leaves a touch of fertilising dust gathered from this or that flower it has previously rifled; so that it is hopeless to expect from any given flower progeny the exact counterpart of the parent without first having taken such precautions for the isolation of plants as it is not easily possible to take in the average garden. Nevertheless, there is such virtue in heredity that, in spite of the bees, you may mark your finest plants in the certain faith that from a good flower, though its offspring may not closely resemble it, you are more likely to get something really fine than from a capsule taken haphazard at harvesting-time.

Nothing that bears on gardening gives me, personally, more delight than to see my Shirleys comfortably "dished" in cool water after they have had their feet in hot; they hit it off so well one with another and make, combined, such a splendid spectrum of colour. This culling of the Poppies is a double gain, for not only have the flowers in the coolness of a jar thrice the lease of life they have on the plant (except in the sultriest of the dog days), but every flower so cut saves the plant an appreciable amount of energy which, to-morrow, will expend itself in furnishing further flowers. Therefore, on my own Poppy borders, I make a raid every morning, if possible before breakfast, to secure the blooms that have opened in the night. These are easily known by the crisp freshness of the petals and, beyond possibility of mistake, by the untarnished purity of the central circle of anthers, which by the evening, if they have not entirely disappeared, will have become discoloured and shabby. Here and there, however, will appear the super-flower (it has appeared this season with embarrassing frequency), which must not be cut, but gathered, together with all its bloom-buds, into a taggot and marked as a seed-bearer with a label setting forth such particulars as may recall to you, at the time of harvesting, the merits of the flower. That I shall have myself by following this plan a plentiful harvest of Poppy seed this year I infer from the fact that I have already (in the first fortnight of July) used up for labels a considerable part of a pack of cards, to the perplexity, I fear, of interested friends, who, seeing only the blarney of the suit, find it difficult to establish a logical

connexion between the harmless Poppy and the ace of spades or the queen of hearts.

To those who are fastidious about the quality of their Shirleys I would speak this word of warning:

"Beware of the 'Blue Poppy.' I do not deny that the Blue Poppy has its fascination. It has. Its colours are quaint to weirdness, and its central tassel of anthers is bewitchingly beautiful, with the beauty which the French so aptly name *la beauté du diable*; for nothing less than devilish

is the demoralising havoc it plays with the Shirleys. On the other hand, anyone who is not strait-laced in his Shirleyism may find a piquancy almost sensational in the vagaries of those dark-anthered Papavera among the fair-petalled Shirleys. I have had the Blue fever myself, and am therefore not unsympathetic; but I have since returned to a saner mind and now am adamant. In my borders an occasional Blue still lifts up its cup; but its shirt is short. SOMERS.

NITROGEN AS A PLANT FOOD

I WAS once called to inspect three houses of young Vines which had been planted six months. The houses were new and splendidly planned, the borders looked in perfect order, the staple being good turfy loam of the right texture, and the Vines were the best that could be procured. These started all right, but when the growths were about bins, in length they came to a standstill and, with the exception of some very dwindling attempts at growth, they were in this condition when I saw them. The man in charge put the failure down to wire-worm. On examination it was found they had started rooting in some old potting soil which had been placed about the roots, but when the roots touched the new soil they would not enter it and they died back. The soil had a very unpleasant smell, and then I was informed that a certain proprietary manure had been mixed with it. There was a talk of a lawsuit with the vendor, but I knew it was procured from a firm of good repute and, as far as could be judged from a sample, it was not the fault of the manure at all, but that an overdose had been given. Some Peach trees planted in the same kind of soil without the manure had done splendidly.

A good portion of the border was removed and replaced with fresh soil in which new Vines were planted. These did well for a year or two till the roots reached the obnoxious mixture, when there was a sudden stop. I visited the same establishment professionally a few years later, when it was in charge of another gardener, and the whole border had to be renewed and planted afresh. Since then excellent results have followed.

The example of the Peach trees shewed that the soil was rich enough without any addition of nitrogenous matter, and when such a soil can be procured I advise no stimulating material to be added during the first two or three years, though it is always advisable to add old mortar or lime in some form, as well as phosphates and potash. Unfortunately, most of us have to make shift with a much less perfect material.

On another occasion a house was planted without any added nitrogenous matter. The Vines grew very strong, but the growth was rather flabby, and at pruning-time the pith was found to be black in colour. Soon after the fruit had ripened the skin turned soft as the pulp and the fruit soon decayed. The cause of this was that turf with long grass growing on it had been used for the border, though not till some months after cutting. The grass heated, however, and caused rapid decomposition of the fibre, so that what should have lasted for two or three years was brought into action all at once. There was also found to be a deficiency of lime in the soil. This was quite unexpected, for the spot was situated between two hills less than three miles apart, which produced excellent lime in large quantities. After a time, when sufficient newly slaked lime had been added to sweeten the soil throughout, all went well.

Two lessons may be learnt from these mishaps. First, that when the sods are covered with long grass it is advisable to char them. It is not often that such a thing happens, but in this case the turf was cut from a large park where there was little grazing other than that done by the deer. The second lesson is that when dealing with a soil with which we are unacquainted it is well to add some old mortar for fruit borders.

With regard to nitrogen, do not imagine that I recommend starving plants. In attempting to produce great results I feed them up to danger point, but it is necessary to know when they will bear the fattening process with the least danger. When I had the privilege of helping myself to undiluted urine from a tank inside a cow shed, it was used freely both indoors and out without any added water during the early winter. When the soil is full of roots it is astonishing how much of such liquor fruit trees and Vines will bear during the dormant season. It must not, however, be applied undiluted later than six or eight weeks before growth starts afresh.

When it is no longer safe to use it on fruit-bearing plants the liquor can be poured in between the rows of Cabbages, supposing these are 2ft. apart and the plants earthed up. These and also Asparagus will bear a great deal of feeding. When no manure water was at hand, I have given well established beds of Asparagus, after growth had started, 1lb. of nitrate of soda to the perch at intervals of only a week, up to midsummer, with good results when there was no deficiency of the other requisites in the soil. To apply nitrogen alone, to a soil which is deficient in other elements of plant food, is to court disaster. But as artificial or concentrated nitrogen disappears more quickly than the other necessities, it is well to apply it in small and frequent doses and only during the growing season. WM. TAYLOR.

A DESIRABLE OXALIS

THOUGH a comparatively common member of its beautiful race, *Oxalis floribunda* is still one of the most attractive and generally useful. In the best forms the pale green, silky-haired leafage of this species is large and handsome making a bold tuft some oins. in height and 1ft. or more across. Well above this rise the ample heads of lovely blossoms, which are rather over half an inch in diameter individually and of a full-toned, satiny rose pink. These are borne in the greatest profusion, a succession being maintained from June to the end of summer. The variety *alba* of this *Oxalis*, though smaller in all its parts, is a most desirable little plant, its clear white, starred blossoms having a yellow eye. *O. floribunda* does not appear to be hardy everywhere, but it is provided with a free, warm soil it should prove long-lived in all but our bleakest climates. A notable feature of this plant is that old-established clumps never seem to shew any signs of deterioration.

CORRESPONDENCE

ROSES AND ROSE SHOWS.

THE heat and moisture of the first half of July have worked wonders in the Rose garden, and one looks back with pity on the starved and stunted blooms that were shewn at the great Rose Show held in London last month. Surely it would be wise for the National Rose Society to make, if possible, an alternate date in future years? The contrast between the glorious blooms now in beauty and those that struggled to expand in June makes it quite clear that the best Roses were not represented. A rose show is for the exhibition of beautiful Roses we all know, but it is the newer and the untried varieties that are the most interesting. A show of Caroline Testouts, Druschkis, General McArthurs and many other well known Roses would not excite the attention of the keen rosarian at a show, though he might welcome them in his own garden. To those who admired the splendid blooms, say, of Lady Ronald-way at last year's show the flowers exhibited this

suggestion to Rose exhibitors and growers.
E. H. WOODALL.

ROSA HUGONIS.

I AM afraid the Rev. Joseph Jacob (page 349) has asked me a question that I cannot answer regarding the flowers of this Rose not opening. But if the unusually cold weather of June was not responsible for the tiding alluded to, I can only suggest that the stiff soil in which the Rose is growing is not congenial to it. The best and freest specimens of R. Hugonis I have seen have all been in very light, warm and sometimes even rocky soil. That this species delights in heat there is no doubt.—NORTH WALES.

A FINE OLD WISTARIA.

I THINK that the enclosed picture of Wistaria chinensis growing on Museum No. 2 at Kew will be of interest to readers of THE GARDEN. Seldom, if ever, has it been seen with such a

A TORRENT OF WISTARIA.

year were a painful surprise, and yet *faute de mieux* they were awarded first prize. How very different it would be if they could be shewn now! The wonder of that show to me was the blooms of the new Rose called after Princess Victoria, which alone looked as if they had opened under favourable conditions. That Rose must either be of extraordinary hardiness or coaxed out by some clever meteorologist who knew how to bottle up the sun's rays for his own special benefit. One longs to see it again! while many others were so far below their usual standard that it was grievous to see them so held up to public shame. Apart from this accidental season, however, it seems to me that the number of good Roses is so vastly increased that it is urgent that a fresh classification should be made, and Roses of more than ten years standing should for show purposes give way to more modern raisings. In that way we should see what real progress has been made, and I suspect that many new varieties would fail to pass the standards of the old? "Old versus New" would make an attractive heading to many a show catalogue, and I put out this

profusion of flowers. This is probably one of the original plants introduced into the country some hundred years ago. Its branches extend along the wall some 40yds. or more, which will give an idea of its value as a climber for covering large spaces. Wistarias are not at all particular as to soil, but will flourish in any good mixture of a loamy nature and grow fast when established. They are most readily propagated by layering the young growing shoots during the summer months, to be detached the following year when they have made plenty of roots. Old plants require little attention beyond spurring in the long shoots soon after they have done flowering. This Wistaria is called the Chinese Kidney-bean Tree. The long racemes of mauve-coloured flowers are produced in May and June. Of this species there are three varieties in cultivation flore albo (white), flore pleno (double) and a form with variegated leaves. Another beautiful plant is Wistaria multijuga, which is of comparatively recent introduction. It has long racemes 2ft. or more in length, but the pale violet flowers are set further apart on the stems than in W. chinensis. It

flower some three weeks later than the older plant and flourishes under the same conditions. Of this also there is a pure white-flowered variety. W. multijuga is the Wistaria that is so popular in Japanese tea gardens with the long, elegant racemes hanging from the branches.—W. L.

PLANTS WITH LEGENDS.

I WONDER whether "An Old Subscriber" (page 363) has heard any of the legends connected with the wild apple blossom? Some of these were exquisitely told by the late Mr. Sharp, writing under the *nom de plume* of Fiona Macleod. There is the old Gaelic legend how "Ana the most ancient goddess, the Mother, made man out of rock and sand and water, and then made woman out of a wave of the sea, the foam of apple blossom and the wandering wind." And another tale of the same flower how "Ulad gathered the Apple blooms and held them to his heart, and at day-break they became a woman, Fand Fand, whose laughter the storm thrush caught long, long ago, and at the end she became once more a drift of white blossom on the deerskin, but some of the blossoms were stained by the wandering fires of a rainbow that drifted out of the rose-red thickets of the dawn." The same writer gives a Gaelic folk tale of the quaking grass in the Garden of Gethsemane, how "among the trees and grasses and birds there were those who doubted, saying 'It is but a man who lies here. His sorrow is not our sorrow,' and Christ looked at them and they were shaken with grief, and that is why the quaking grass and the aspen are forever a-tremble, and why the wagtail quivers along the earth like a dancing shadow." The Pimpernel was good to prevent witchcraft if gathered early in the morning in a churchyard, saying "Rise up pimpernelle and goe with me, and God shall bless me, and all that weare thee. Amen." Miss Teresa Hooley has told the legend of the Galium in graceful verse, "Our Lady's Bedstraw":

"Through the fields came Mary Mother
In the twilight dim and grey:
All the dew wet grasses quivered,
All the wild flowers bent one way.
Night drew down all cool and quiet,
Mary Mother sought to rest,
Slept upon a bank of blossoms—
Yellow spirals, fragrant, blest."

"An Old Subscriber" has a fascinating task in collecting the legends pertaining to plants and flowers.—J. P.

CAMPANULA MIRANDA.

UNDER the name of C. Bellardii Miranda this pretty little plant gained an award of merit when exhibited at the Cardiff Show in July, 1920, by Mr. Clarence Elliott. In a recent catalogue I find the plant given under the name of C. cæspitosa Miranda, while in general appearance it is very much like a form of C. pusilla. Whatever its botanical designation may be, it is undoubtedly a distinct and nice plant for the rock garden, and the late Reginald Farrer, the introducer, considers it one of his greatest finds. He says "it is going to be one of the greatest of our rock garden plants," and although I cannot agree with this remark to the full; nevertheless, it ought to find a place wherever choice alpine are grown. For two or three weeks it has been a mass of bloom, a patch of several feet being most effective. The plant is dwarf, and the pale blue flowers are only a few inches high, which are produced in quantity. It is easily grown and when established makes considerable headway, while it is readily increased by division. These dwarf Campanulas with their numerous bell-shaped

flowers are indispensable in the rock garden, and they are suitable for various positions. *C. Miranda* is growing between stones along the pathway, but perhaps it is best on a fairly broad ledge at a higher level, where its unique beauty is brought more in line with the eye. T. W. B.

A BEAUTIFUL "LILY."

FEW plants found by the late Mr. Reginald Farrer and other intrepid plant collectors within the last decade or so are more coveted by hardy plantsmen fired with a desire to know and grow the finest hardy flowers or appeal to them more than *Nomocharis pardanthina* Farreri. Possibly Mr. Farrer's glowing account of its discovery has had something to do with this, and there is also the inherent seeking after novelties provided they are good. It appears probable that *Nomocharis pardanthina* may prove hardy with us, and now that it has been put on the market we shall soon learn more about its beauty and its requirements. It has found its way into Scotland, and I saw an apparently exceedingly healthy plant in a bed of peat and loam in the south of that country the other day, and was glad to observe it looking so well after a rather cold spring. It is quite a good-looking plant, even when not in flower, and Mr. Farrer's account of it as he saw it nodding down the slopes of a high alpine pass with its shell pink flowers, which he likened to those which might be produced by a cross between a minor Lily and *Odontoglossum Rossi*, can enable us to imagine what it must be like when seen in generous groups in the rock garden. It is not, however, yet cheap enough to be a plant for the many in such quantities, and the investment in even a single plant will be as much as most hardy plantsmen will venture for a time.—S. ARNOTT.

ROSE REV. F. PAGE-ROBERTS.

IN adding to my modest collection of Roses it has been my invariable practice to know something of a fresh variety before ordering, but last year I was drawn to Rev. F. Page-Roberts by a note which appeared in *THE GARDEN* concerning it, and the order was placed for delivery in autumn. May I say that it has proved all that has been claimed for it, notwithstanding an unusually trying spring. It is a Hybrid Tea that, when in the bud stage, shews a suffusion of yellow and buff veined with pink, but when developed it is a really glorious Rose, full, well formed and is the nearest approach to *Maréchal Niel* in colour and shape that is possible. When one adds to this that it has a fairly vigorous constitution, its designation as an "outdoor *Maréchal Niel*" is not exaggerated. Besides this it is deliciously perfumed. I venture to predict that Rev. F. Page-Roberts has come to stay, and among yellow Roses will take the premier place.—W. LINDERS LEA.

PRIVATE GARDENS AND THE PUBLIC.

IT is a kind thought that prompts the owners of nice gardens adjacent to large towns to open them on Sunday evenings for the public to walk around and enjoy the beauties of the flowers. Such a thought prompted Mr. Louis J. Tillett, J.P., Old Catton, whose pretty garden is situated about two miles out of the north side of Norwich. Hundreds of persons availed themselves of the opportunity to see the glorious Roses that Mr. Tillett grows. The clumps of Sweet Peas were also looking fine in spite of the heat and, together with the herbaceous borders, were a grand sight. A feature that adds much interest is the clear names on the labels attached to all the Rose trees and Sweet Peas. Practically

no damage is done; everyone is a policeman. Let us hope the idea will continue and expand. It brightens the lives of the less fortunate and promotes a love for the beautiful.—AYTCH PEA.

FUCHSIA ENFANT PRODIGE.

WITH reference to the enquiry of your correspondent for *Fuchsia Enfant Prodigue* (page 349), this can be supplied by Mr. Thomas Smith, Daisy Hill Nurseries, Newry. I should also like to advise your correspondent W. Linders Lea, who wrote about *Rose Hiawatha*, to try the *Witch Rose*, *Caprice Rouge*. In regard to *Lilium philippinense*, the form your correspondent "Northern" saw in Wigtownshire is undoubtedly the alpine form named *formosanum*. This has proved quite hardy at the Royal Botanic Garden here and also with the writer in East Lothian.—GEORGE M. TAYLOR, Edinburgh.

THE FOAM FLOWER.

I AM sending you a picture of *Tiarella cordifolia*, so aptly called in English the "Foam Flower." It is a pity that this beautiful little plant is not more generally grown. It is an excellent plant for the wood garden, shady banks or, better still, in a cool, shady part of the rock garden. In June it sends up pinky bare stems on which are borne creamy white flowers not unlike a *Spiræa*. The Foam Flower sends out innumerable runners. Propagation is carried out by taking rooted runners, and this may be done now. This plant prefers a rich, moist soil, but will thrive in almost any soil or position.—C. H.

AQUILEGIA ECALCARATA.

IT seems to me that there might be several species of *Aquilegia* without spurs, as mentioned by "East Molesey," page 349. All of them could bear the name *ecalcarata* without objection and without any technical fault if writers would observe the rule to give the name of the species in which the default occurs. The lack of spurs occurs most frequently in *A. vulgaris*, and this should be written *A. vulgaris ecalcarata*, and so with other species in which it may occur by what we call accidental variation. Only one *A. ecalcarata* is mentioned in the "Index Kewensis," and this I have seen. It was a garden name, recorded in "Stendel's Nomenclature," Ed. II, i, 115, and this was referred to *A. vulgaris*. Even if a wild *Aquilegia* were found without spurs it would, no doubt, be possible by observation to discover the species near by in a normal condition. The lack of spurs should not constitute a new species.—HORTICULANUS.

CLOVER AS A LAWN PLANT.

FOR more than forty years I have been familiar with White Clover (*Trifolium repens*) as a constituent of lawns, and my impressions at the early date was that it was desirable. After the

mowing machine had gone over the grass the Clover was the first to become green afterwards. This was in the flower garden of a private establishment, where tennis and other games were out of the question. Even on a single lawn of some size the soil may vary so greatly that grasses which may grow at one end may not grow at the other. The presence of water and the shade of trees also alter the conditions so much that one must allow different Grasses and even other plants to grow in order to maintain a close green sward. Clover does not wear well where there is a great amount of treading, as might have been seen at the recent Show of the National Rose Society in Regent's Park. The Clover turned black on account of the treading by many hundreds of

THE FOAM FLOWER, *TIARELLA CORDIFOLIA*.

people, but I have no doubt it will be green again sooner than the mown grass. I have noticed Clover remain green by the side of a gravel path in 1921 and this year long after the adjoining grass had turned a grey white. One of my correspondents complained of the seeds sent by the seedsman, not because of the fine grasses that died, but because of the Ryegrass that lived. This puzzled me greatly, because if the Ryegrass had not lived the lawn would have been absolutely bare. Some gardeners and others in charge of grass areas even sow Yarrow with the grass seeds in poor sandy soils in order to get something green. The use of basic slag, mentioned by "S. P." on page 348, would help greatly to prevent patchy lawns of Clover.—J. F.

FORTHCOMING EVENTS.

August 1.—Leves Horticultural Society's Meeting.

August 2.—Royal Lancashire Agricultural and Horticultural Exhibition (four days).

August 3.—Bradford Hospital Fund Exhibition (two days).

August 4.—Illogan Gardening Society's Exhibition.

THE NATIONAL SWEET PEA SOCIETY'S SHOW AT BATH

IN order to be in London next year, when it is expected that the British Empire Exhibition at Wembley Park will bring a large number of interested persons from all over the world, the executive of the National Sweet Pea Society departed from its usual custom of holding its annual shows alternately in London and in the provinces, and again this year had a provincial show. An invitation from the Bath Horticultural Society was accepted, and the show was held in the western city on July 11 and 12. As usual, the great trade exhibits were a very important feature of the show, and it is safe to say that such magnificent groups, made up of thousands of splendid spikes of Sweet Peas, had never before been seen in the West of England. Although Bath escaped the devastating storm which swept over a large portion of the South a couple of days previous to the opening date of the show, the weather was oppressively hot, and soon after noon on the second day of the show the Sweet Peas were flagging badly.

There were ten entries for the City of Bath Challenge Cup—this section required an exhibit of Sweet Peas grown out of doors without any protection or shading, arranged in a space 12ft. by 4ft. 6ins.—but on account of the weather conditions just one-half were withdrawn on the day before the show. The Challenge Cup was won by Mr. J. S. Stevenson of Wimborne with a superb collection, containing many of his own novelties, which were arranged very tastefully. This fine group was also awarded a large gold medal. Messrs. R. Bolton and Sons, Baythornd, Halstead, Essex, had a very artistic display. They used goodly sized gilt baskets which, raised a different height, had a most pleasing effect, and they were awarded a gold medal. A similar award was made to Messrs. E. W. King and Co. of Coggeshall for an imposing group of first-rate Sweet Peas. Messrs. Sutton and Sons, Reading, also arranged a first-rate collection and received a gold medal; while a silver medal was awarded to Messrs. S. Bide and Son, Farnham, for a pretty display.

For the Eastbourne Challenge Cup there were originally eight entries, but by force of weather conditions two of them found themselves unable to fill the 15ft. by 4ft. 6in. space which is required. The cup and large gold medal were awarded to Messrs. Ireland and Hitchcock, Mark's Tey, for what was probably the most imposing display of Sweet Peas that has ever been shewn. It was made up of generous masses of distinct varieties—often nearly a yard across—and their magnificence captivated a great many of the visitors. Messrs. Dobbie and Co., Edinburgh, had an exceedingly graceful group of well grown Sweet Peas, but as the judges found that, unfortunately, the allotted space had been exceeded, this did not enter into the cup competition, but was awarded a large gold medal for its attractiveness and quality. Messrs. Carter and Co., Raynes Park, received a silver-gilt medal for an elegant arrangement. Mr. G. Morbey, Aylesford, and Mrs. P. Warner Abbott, Hailsham, were awarded silver medals for their exhibits.

There were five sets of twelve vases in not fewer than six varieties, raised or introduced by the exhibitor, in competition for the Monro Challenge Trophy. The best were set up by Mr. J. Stevenson. Messrs. Thomas Cullen and Sons, Witham, Essex, were second; and Mr. H. J. Dameruni, Hayling Island, third.

The Burpee Cup was again won by Messrs. E. W. King and Co. with a very graceful stand

of Waved Sweet Peas in such varieties as George Shawyer, Valentine, Orchid, Royal Scot and Picture.

The raisers' class, which requires six vases of distinct varieties raised by the exhibitor, created a little mild excitement when it was found that the judges, unable to decide between the three competitors, had placed them equal first. Mr. J. Stevenson included Grandeur, very attractive rose purple shades; Cynthia, pale lavender blue; and Wild Rose, rose pink shaded with salmon orange on the standards. Messrs. Thomas Cullen and Sons shewed Champagne, Lucifer and Purple Perfection; while the best shewn by Messrs. E. W. King and Co. were Rosy Morn and The Sultan. The latter was such a dark maroon as to suggest that a black Sweet Pea will be evolved in the near future.

Mr. J. Stevenson had the best three vases of new seedlings. He shewed Grandeur, Felicity (blush pink on white ground) and Charming (deep rose pink). With the last-named variety he was also first in the class for one vase of a new seedling.

The Carter Challenge Cup class was disappointing, as the judges did not find a blue Sweet Pea worthy of the award, so this handsome cup has yet to be won for the first time.

AMATEURS' EXHIBITS.

The quality of the blooms in most of the amateurs' exhibits was exceedingly high, so much so that the judges found the "best vase in the show" among them. This was a magnificent vase of Matchless in the Stevenson Cup collection of novelty Sweet Peas by Sir R. Baker, Bt., who has long been an exhibitor of first-rate Sweet Peas. In this class he also shewed Dignity, Wild Rose, Burpee's Giant White, Powercourt, Edith and The Sultan.

The *Daily Mail* Cup class, which requires twelve vases of Sweet Peas already in commerce, is always keenly contested, and this year it was won by Sir R. Baker, Bt., with a magnificent collection of such sorts as Fair Lady, Valentine, Unwin's Crimson, Constance Hinton, Royal Scot and Hercules. The Sutton Cup was also won by Sir R. Baker, and here, among his eighteen vases, Tangerine Improved, Mrs. T. Jones, Matchless, Conquest and Le Mahdi were superb.

The Cory Cup was won by Mrs. Shirley Woolner with six beautiful vases of Sweet Peas; while the President's Cup, which is in open competition, was won by Mr. A. O. Cosham with an excellent collection, and in the same section Miss Russell won the E. W. King Cup with twelve splendid vases.

Generally the district classes were well filled, though Ireland only had one entry, and for, at least, the second year in succession there was no entry in the Scottish class. But this year, in view of the great distance and the fact that the date is full early for northern growers, Sweet Peas from over the Tweed could scarcely be expected. The first prize in the Southern class was won by Sir R. Baker, Bt., with one of his superb exhibits.

The colour classes, which require one vase of any variety of the stipulated colours, formed a very attractive feature of the show and nearly all the vases were of considerable merit.

The decorative classes did not bring forward any novel method of arrangement, but there were nine very attractively decorated dinner-tables. The first prize was awarded to Mrs. A. R. Bide, who is consistently successful in such classes, on matter what flower she uses. Mrs. A. D. Ruff,

another well known successful exhibitor, won the first prize in the class for a decorated basket of Sweet Peas, and Miss Gladys Burt won the first prize with a delightful bowl of Sweet Peas which was considered by many to be the most attractive exhibit in the decorative classes.

Gardening of the Week

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Potatoes.—The early crop may be lifted, and if the skins are tender the work should be done carefully to prevent any injury. When this work is finished clear the space of weeds, level it with a fork in readiness for Spinach, Turnips and other crops.

Seakale.—The thongs planted out last spring are making progress, and shoots should be reduced to one to each thong. A light dressing of salt will be beneficial.

Winter Onions.—This crop will be approaching maturity, and when the tops have ripened off the bulbs should be lifted. Before transferring them to the store shed they should be thoroughly dried and ripened, which may be done by placing them on a gravel walk or in similar position. If stored dry they will remain in good condition for several months.

Spinach.—For standing the winter, sowing of the prickly-seeded variety should now be made, selecting a piece of ground that has not been manured recently and is not likely to become very wet during the winter months. The seeds should be sown thinly in rows 15ins. apart, and when the seedlings are well advanced thinning must be resorted to. Keep the soil well hoed and the crop free from weeds.

Asparagus.—An occasional examination of the growths will be necessary to prevent injury from rough winds. Remove all weeds, and when rain occurs a sprinkling of artificial manure may be afforded.

Globe Artichokes.—When this crop is finished the stems should be cut out and the soil between the plants forked over. This is a plant that gives very little trouble.

Mint and Parsley.—A few rows of the latter and a portion of the bed of the former may be cut down to the ground-level with the object of securing young growths some weeks hence. The Parsley will then keep better through the winter months.

The Flower Garden.

Shrubs.—Many shrubs can be increased by layering, and they include Rhododendrons, Azaleas and Crinodendrons. Select growths that are near the soil, and when the branch has been partially severed it should be split with a knife in an upward direction for 2ins. or 3ins. Make a slight depression in the soil. Peg the cut portion down firmly and cover with earth. As a rule they take a long time to form roots, and the layers ought not to be severed from the parent plant until they are well rooted.

Climbers.—Ornamental Vines, etc., growing on arches, poles or pergolas will need a little attention to keep the shoots in order, while any that may be overhanging walks should be removed. Creepers growing on the walls of the dwelling-house should be tied up where needed, and shoots of Wistarias, if not required for extension purposes, may be shortened to within 6ins. of the stem. The new growths of Rambler Roses situated near lawns or grass walks should be tied loosely to the poles to prevent injury from the mowing machine.

The Rock Garden.

Propagation.—At this season a few cold frames are set apart for propagating plants for the rock garden. The frame should be stood on a hard base and then about 6ins. or 8ins. of sandy soil placed in the frame, when it is ready to receive the cuttings, which should be set out in lines 2ins. or 3ins. apart. Keep the cuttings sprayed occasionally, and if the weather is bright a little shade will be necessary during the middle of the day. When they have rooted admit plenty of air and light. Such plants as *Helianthemum*, *Saxifrage*, *Pinks*, *Androsaces*, *Verbenas*, *Daphne Cneorum*, *Phloxes* and almost any other plant may be tried if the growth is available for the cuttings.

The Hardy Fruit Garden.

Peaches and Nectarines.—In many gardens the crop of both Peaches and Nectarines is practically nil, but where fruit is present it should be fully exposed to the sun. Young growths should be tied in as the necessity arises, and any strong gross shoots removed, for they are of little value; and, moreover, they often take the lead to the detriment of the smaller growths which form the fruiting wood next year. Any trees that are producing a quantity of extra strong shoots should be examined in the autumn with a view to root-pruning. If the weather is dry, the roots should be afforded a thorough soaking of water, especially those trees producing a crop of fruit. In hot weather the foliage may be well syringed in the afternoon, which will also hold in check red spider. When the fruit is gathered the trees should be thoroughly washed, using the syringe or garden engine.

Fruits Under Glass.

Vines.—Unless Muscat Vines are started very early and the season is exceptionally good a little pre-heat will be necessary to ensure perfect ripening of the bunches. A night temperature of 55° to 70° should be maintained, with a rise of 10° or so during the day. A rather dry atmosphere is needed, but if the weather is fine an occasional damping down of the floors will be necessary. Free ventilation is advisable, but this ought not to be overdone. A little from the top ventilators will be found more beneficial if left on both day and night rather than allowing the house to become excessively hot and then opening them to their fullest extent. Prevent, as far as possible, any moisture on the berries which will cause them to "spot." Keep the border well supplied with water, and where this is properly constructed with plenty of drainage there is little danger of overwatering when the Vines are in a state of activity.

Cucumbers.—If a house or frames are available, a few Cucumber plants may be set out with a view to securing a supply from September till late autumn. A hot-bed should be made up for the frames, and later on it will be necessary to add a thick lining of fermenting material to keep up the temperature.

T. W. BRISCOL
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chesham, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Potatoes.—When selecting tubers of the early varieties for seed, retain those of second size and expose them to full light until they become slightly green before storing them. Make sure that the tubers are perfectly dry before storing. Put them in a cool, dry place where there is a free current of air.

Peas.—If the weather proves dry, give the later sowings a liberal supply of water, after which run the Dutch hoe through the soil to slacken it and apply a moderate mulching of whatever materials are available. Grass mowings, old hot-bed manure or pure half-decayed leaves are suitable for the purpose. The mulch serves to conserve moisture and to keep the roots cool.

Brassicas.—The various members of the Brassica tribe which were planted last month will now be benefited by drawing a little earth up to the stems with the draw hoe.

Jerusalem Artichokes.—These tall-growing plants if allowed to develop at will on heavy, rich soils are apt to be damaged by the September gales, so where they are growing under the conditions indicated it is advisable to top the plants when they have attained a height of 5ft. or thereabouts. Another precaution which may be taken against damage is to drive in a few stout stakes round the quarter and run a stretch of binder twine round the crop at a height of about 4ft.

Globe Artichokes.—If all the produce cannot be utilised, cut away the heads before they show flower, but if cut while in a fit state for using and stood in a shallow vessel containing water, plus a little salt and placed in a cool, shaded position, they will keep in good condition for a considerable time.

Fruits Under Glass.

Strawberries.—If the work of layering was taken in hand early in June, the young plants, whether in pots or turf squares, should now be ready for potting up. The potting material should consist chiefly of sound fibrous loam, to which may be added a little bone-meal. Avoid quick-acting fertilisers, the object being to build

up a vigorous yet compact plant with a strong crown and leathery foliage. Ram the soil fairly firmly, and leave sufficient room for water, and those who practise top-dressing in spring should make further allowance for this. Stand the plants on a layer of coal ashes where they will receive the maximum of sunshine, and attend to the watering regularly, as the least check will militate against their ultimate success.

Early Vines.—If the entire crop of fruit has been gathered, the Vines should be thoroughly cleansed with the garden engine or syringe. Afterwards they should be given a liberal supply of water at the root to enable them duly to perform their various functions until the wood is perfectly ripened, a process which is essential to the production of a good crop of fruit next season. Ventilate the house freely day and night consistently maintaining a temperature of from 60° to 70° meanwhile.

The Flower Garden.

Crocus speciosus.—In the wealth of variety of the common spring Crocus, *C. vernus*, the distinct species have been pretty well crowded out of the modern garden. *C. speciosus* should, however, be accorded room of a greater or lesser extent in every garden, it having three features to recommend it: First, its beauty—it has bright lilac petals lined inside with dark purple and prominent rich orange anthers; secondly, it is easy of cultivation, increasing rapidly if the conditions are at all favourable; and thirdly, it is an autumn bloomer, when it strikes a distinct note in the mixed flower border. Plant as soon as possible.

Colchicums, often erroneously called Autumn Crocuses, should find a place in every garden, as they are highly attractive during September and early October. The two best are *C. speciosum* with large reddish purple flowers and *C. Bornmulleri* with large lilac flowers and white centres. The common Meadow Saffron, *C. autumnale*, is suitable for the front of the shrubbery or for naturalising, but some of its varieties, such as the double purple and double white, are worthy of a place in the garden. The corms should be planted about 3ins. deep during the first half of August and will then flower in a few weeks time. Once planted they may be left undisturbed for a number of years.

Dahlias will now be making rapid growth, and attention should be given to thinning out surplus shoots and tying up those retained. This latter operation is best done by looping them up rather loosely, as all appearance of stiffness should be avoided. The earwig traps, of whatsoever kind, should be regularly examined, and any prisoners caught should be destroyed. Unless the soil is in very good heart an occasional dressing of some stimulant should be given, choosing showery weather for the operation.

The Rock Garden.

General Work.—If planting was judiciously carried out, there will still be a fair amount of colour here, and where it is lacking a resolution should be made to improve matters before another season. A judicious selection of annuals helps greatly to prolong the beauty of the rock garden. Save seed of any plants which it is intended to propagate. Certain plants, although perennial, should frequently be renewed from seed, otherwise they become leggy and unsightly; *Dianthus* and *Primulas*, for example. Cut away all decayed flower-stems, and bare patches of soil should be pricked with the handfork. If the weather is dry, watering should be resorted to, choosing the afternoon for this work.

Seed-Sowing.—The sooner after ripening the seed of rock plants is sown the better, as many of them lose their vitality partly or entirely in a comparatively short time. The seed should be sown in shallow, well drained pans or boxes. The soil used should vary with the character of the plant. *Primulas* may have moderately rich soil; others, again, require peat; while not a few prefer poor, gritty soil. The pans or boxes should be placed in a cold frame, and the latter kept close and lightly shaded until germination takes place.

CHARLES COMFORT
(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mans, Midlothian.)

GREENHOUSE AND CONSERVATORY.

Aotus gracillimia.—This beautiful Australian shrub may easily be propagated at this time by means of the more slender twiggy shoots inserted in pots containing light sandy soil. The cuttings soon root if stood under a bell-glass in a cool

house. Owing to its slender drooping habit this plant is seen to best advantage when grown as a standard. For this purpose the young plants should be stopped once, then two or three shoots from the first break should be selected to form the stem of the standard, which should be some 2½ft. to 3ft. in height. All laterals should be kept rubbed out until the desired height is attained. The leading shoots should then be stopped and the laterals allowed to develop. After flowering is finished each spring, the long, slender shoots should be pruned hard back and the fresh shoots allowed to grow without any stopping. This plant only requires cool greenhouse conditions during all the stages of its cultivation. It is not by any means a long-lived plant, therefore it is advisable to root a few plants each year.

Prostanthera rotundifolia is another Australian plant that is very useful for the cool greenhouse. In the South and West it is more or less hardy against a warm wall, and thus makes an excellent plant for an unheated house. Unlike many of the hard-wooded plants, it is not difficult to propagate, cuttings rooting readily under a bell-glass in a cool greenhouse or cold frame. This plant should be stopped several times to induce a good bushy habit. Excellent examples for the stages can be grown in 6in. pots, and this plant also makes a fine specimen if planted out in a bed or border in a cool house. Under such conditions it produces its rosy purple flowers in wonderful profusion. After it has finished flowering in the spring the strongest shoots should be partially pruned back. Although a strong, free-growing plant, I find that it resents the use of the knife, especially so in the case of pot-grown plants, and after a few years refuses to break freely. This, however, is not a very serious matter, as it is easily propagated and grows quickly.

Primula malacoides.—If not already done, seed of this elegant and useful *Primula* should now be sown. Excellent specimens can be produced by growing several plants in shallow pans. On the other hand, perfect little specimens are obtainable in sixty-sized pots, and such small plants are very useful for table decoration and decorative work generally. This *Primula* is nearly hardy, and can be grown perfectly well in cold frames until winter, when it is advisable to transfer to a cool, airy greenhouse, as it is somewhat liable to suffer from damp, especially in this neighbourhood, where we get so little winter light.

Primula Forbesii is a very dainty plant, and is well suited for a small unheated greenhouse. Seed of this *Primula* is best sown towards the end of August or during September. The best results are obtained by growing four or five plants in forty-eight-sized pots.

Primula Cockburniana may also be grown in the same way, and with its brilliant orange yellow flowers is a charming plant for a small unheated house. The same applies to *Primula Veitchii*. This is a larger-growing plant and is well suited for the ordinary greenhouse.

Primula cortusoides, of which there are many fine varieties, is also a fine *Primula* for the unheated greenhouse. All the named varieties are increased by division, and this operation may very well be done at this time. Forty-eight-sized pots are quite large enough, and a frame with a north exposure will suit the plants best during the summer.

Other Primulas.—Although quite hardy, *Primula japonica*, *P. pulverulenta*, *P. Bulleyana* and *P. Beesiana* and their many beautiful hybrids or varieties all make excellent pot plants, and are worthy of more attention for the unheated greenhouse. They are all large-growing plants and enjoy generous treatment, including plenty of water at the root. They are best grown outdoors in a cool, moist position during the summer, when they should make fine large plants, which during the autumn, may be lifted and put into suitable-sized pots. Afterwards they should be kept in cold frames during the winter.

Liliums in Pots should be kept plunged in a position where they will receive some shade for at least a portion of the day. They require strict attention as regards watering, while the stem-rooting species and varieties should be top-dressed with some light rich soil. A portion of them, according to requirements, should be introduced to a greenhouse. *L.L. auratum* and *speciosum* and their varieties are usually grown for this purpose, and may be had in flower over a long period. *L. Henryi* should be more generally grown for conservatory decoration, as it is specially useful in large houses. *L. regale* is a splendid pot Lily, and is sure to be grown in large quantities when the price is more reasonable.

Royal Botanic Gardens, Kew. J. COUTTS.

SOME NOTABLE PLANTS OF THE LATER SUMMER

THE Mertensias are a select race, none of them being common in gardens, but because we cannot give them the root coolness which they seem to demand the majority of the later-flowering species are not happy with us. The lovely *M. virginica* can be coaxed along with patient care, but slugs are allied with drought in the persecution of this charming thing. *M. sibirica* (ciliata), however, is tolerably content in a comparatively cool border, and its pale emerald foliage and tassels of opaline bugles together make an object that is pleasing to look upon on a hot July day. This plant, moreover, sows its own seed, so that if the parent perishes, as it frequently does, the young are there to carry on.

How striking the contrast between this rather frigid-looking plant and the blazing colour of that sun worshipper *Pentstemon barbatus coccineus*, for which no soil is too poor, no place too dry! The pale green flower-stems of this striking perennial sweep upward from a spreading tuft of narrow, fleshy leaves to the height of a yard, and are hung with vivid coral-scarlet tubes throughout the later days of summer. *P. barbatus* is also known as *Chelone barbata*, and there are several varieties, all of them extremely showy. One or two *Pentstemons* of the glaber class and some hybrids with a sisterly resemblance to *P. alpinus* can boast of the extraordinary metallic blue which distinguishes the better-known *P. heterophyllus*, and any or all of them are well worth a trial in free soil and a warm, open situation.

Most of the *Oenotheras* must be numbered among the chosen when speaking of late-blooming plants, for they are not only very beautiful individually but invaluable at a season when so many things are passing off. Admirable in every way as its compatriots are, I think the award for highest merit in this group must go to *O. caespitosa* (marginata). This species is much after the style of *taraxacifolia* and *macrocarpa*, but it does not trail and its fleshy leaves, with the reddish midrib, are waved or bluntly toothed rather than deeply indented as in the *Dandelion* pattern. *O. caespitosa* does, however, move about by underground runners and sends up at intervals an 8in. tuft of foliage. The blossoms borne by this splendid species are often gins. across, a spotless white and richly fragrant. Like most of the white *Oenotheras*, these superb blooms become gradually suffused with fresh rosy flush soon after maturity is reached and die off in a deep flesh pink. Though *O. caespitosa* is a true perennial and hardy enough for most places where the drainage is good, it is susceptible to excessive winter wet. But even though the main plant may succumb to this cause, the young off-sets generally manage to survive.

Lavendula dentata is a comparatively new Lavender of robust growth with broad, fresh green leaves, deeply veined and serrated. This foliage is very fragrant at all seasons, and the stout flower-spikes, which attain a height of some 2ft., terminate in bold heads of blossom. These often appear quite early in spring and remain until late summer. Although the individual flowers are small, the plant makes amends for this failing by enveloping them in large triangular bracts of a rich lavender hue, the brightest and largest standing up at the tip of the spike as in the old-time *Clary*.

For a light soil and a sunny position *Lavatera Olbia* is a sub-shrubby plant of remarkable beauty, making a fine and hearty bush some 4ft. to 5ft. in height and as much across. The large, mallow

like leaves are roundly lobed and a grey-green owing to the nap of fine hairs which covers them. Few of the later summer perennials will maintain such a long succession of flowers, and these in such extraordinary numbers, as *L. Olbia*, and a well grown specimen with every tapering branch bearing quantities of the large cup-shaped blooms, clear rose, with deeper veinings and as large as those of a *Hollyhock*, is a most arresting object. Though *L. Olbia* never sets seed with us, it has proved perfectly hardy and long-lived under some trying conditions. By cutting the plant back to the base in spring the flowering season is thrown rather later than it might otherwise be, but such treatment tends to a more shapely growth, finer foliage, larger flowers and more of them.

These last remarks are applicable also to the great *Romneya Coulteri*, which is without a peer in the garden from July to autumn. This magnificent plant, though growing in the most impoverished of rocky soils, will throw up a forest of stately canes to 8ft. or 9ft. after the cutting back in spring. And though it rarely gets any attention beyond this severe decapitation and the pulling out of superfluous suckers, it will yield its enormous blossoms in the greatest profusion over the period named.

Growing in similar soil and in some instances on the arid and stony ledges on the top of low retaining walls is another Californian, *Diplacus glutinosus*. This is a trifle tender inasmuch as it is liable to get its tips pinched by frost if it is indiscreet enough to continue flowering right on to the brink of winter, as it is apt to do. But this does little harm, since *D. glutinosus* also enjoys being pruned back in April. At the time of writing we have several groups of this splendid shrub glowing with their burden of beautiful golden buff flowers, and this amazing show of blossom will continue, as I have suggested, until late autumn. In addition to this typical form there are several kinds of *Diplacus*, some being paler in the flowers, approaching creamy ivory, others deepening to burnt orange, one or two of them being accorded specific distinction. All are good, and since cuttings strike so readily and grow so fast, it is an easy matter to keep a stock in reserve when there is any doubt as to the established plants standing the winter.

Among the dwarfier members of the house of *Lathyrus* the annual, *L. azureus*, is choice and uncommon. We generally sow the seed in the spring where the plants are to bloom and provide a few short sticks for support. The seedlings grow freely, and from July onwards produce a succession of pretty turquoise blossoms about 1in. across right on to September. The seed-pods are curiously winged and their wedge-shaped

contents usually ripen satisfactorily. Another little *Pea*, which is too good a thing to ostracise even if it can be a pestilential thing in the wrong place, is *L. tuberosus*. Given a spot where it can spread and ramble at will, this engaging wanton will climb to 4ft. or make tendril-bound masses of its pale green and elegant foliage, which throughout the later months of the season will yield a profusion of fragrant flowers in clusters of six or seven and of a full-toned rose pink. Once established *L. tuberosus* will outlive Methuselah and every recurring year win over again your admiration of its cheerful flowers and commendable good temper.

The *Flame Nasturtium* (*Tropaeolum speciosum*) might be bracketed with the above, not that it is very often a pest, but because, once it has made itself at home, it will take care of itself for ever and continue to increase in vigour and beauty. Though we started it against a north wall, which it now partly shares with *Berberidopsis corallina*, it has gradually worked its way into an adjacent thicket of *Azaleas*. The topmost branches of these it festoons with its brilliant scarlet wreaths throughout the later summer and autumn. It runs up the stately stems of *Lilium Henryi*, weaves ropes of bright colour about the gloomy green of *Pieris formosa*, and one of these days it promises to enliven with its happy garlands the sombre verdure of an ivied wall. *T. speciosum* is a jewel beyond price, a plant worth any amount of patience in establishing. Its seeds, which often go unobserved though as large as small peas, are a clear china blue, and those who have propagated by this means contend that they should be sown as soon as they are ripe, i.e., in autumn.

Erodium as familiarly known, and which the learned proclaim as a garden variety (*luxurians*) of the Pyrenean species of that name, is one of the most trustworthy of late bloomers. Faults it may have in plenty, being only mortal, but its cardinal sin is no more than the rather strident tint of its crimson-magenta flowers, none but the *dilettante* need grieve. To the average gardener *E. Manescavi* is a fine and hearty plant which with the best of good temper, will make a mass of most elegant, dark green, ferny leafage under summer conditions that cause the majority of plants to fold their wings. The striking heads of flowers, which resemble a *Pelargonium*, are borne at the ends of 18in. stems, and these are yielded in extraordinary abundance throughout the "back-end."

Put into a border of well drained but not too dry a soil as an experiment a few years ago *Lobelia Cavanillesii* has done wonderfully and proved a deal more reliable than *L. cardinalis* or *L. syphilitica*, both of which have a way of disappearing in winter under the same conditions. *L. Cavanillesii* (which I am assured is really a form of *L. laxiflora* and ought to be labelled *L. l. angustifolia*) is a 1ft. slender plant with long and narrow, willow-like leaves very slightly toothed.

Always Kelways
FOR
THE STATELY GLADIOLI

When seeking information or prices, write direct to:

KELWAY & SON, The Royal Horticulturists, LANGPORT.

For many years we have been the leading Specialists in these glorious flowers.

The flowers, which appear at the axils of the uppermost leaves, are in the bud a brilliant orange-scarlet and about 1 in. long. But when they have elongated to about twice that length and opened into the semblance of the yawning bill of some strange and gorgeous bird the predominant colour is a gleaming yellow. The flowering season extends from July to autumn, and as the plant runs freely increase is a simple matter.

Though it is not the prettiest of the minor Fuchsias, there is a fascination about the curious little *F. procumbens* which never fails to attract notice. A perfectly prostrate species, with heart-shaped leaves in a soft apple green and long trailing branches which delight in threading their way unobtrusively about other plants, *F. procumbens* is a gentle and pleasing occupant for any fairly cool rock garden ledge. But its most interesting features are the blossoms which it produces so liberally. These can be likened to nothing that ever was on land or sea, but they might be described as tin tubes of glistening, honey-coloured wax. The tiny triangular petals of chocolate brown are sharply reflexed and quite out of proportion to the size of the tube, and each has at its base a daub of arsenical green. When these weird creations have fulfilled their destiny they give place to fruits which, from the size and likeness of green peas, swell to the dimensions of a small, fat gooseberry and ripen a deep plum red. *F. procumbens* is a deciduous species not only as regards the leaves, but its trailing summer growths also die back to the base in winter. In regard to its hardiness I can only say that it is rather more reliable than most of the dwarf Fuchsias usually listed as hardy. A. J.

LATE SUMMER SEDUMS

WHEN the enormous golden flower-heads of *Sedum compressum* are at last beginning to tarnish, having maintained their unrivalled splendour for some ten weeks, many of the later species are coming into bloom. Conspicuous among them is *S. pulchellum*, a hardy American whose pretty glaucous leafage, often flushed with crimson, is to the eye of the average observer after the pattern of that of the familiar *S. reflexum* of our old walls and hedge banks. But the leaves are finer and paler in colour, rounded at the tips and forked where they meet the stem. *S. pulchellum* is, moreover, a species which enjoys considerable moisture and a cool root-hold, even delighting in the proximity of water. The flowering stems ascend to some 4 ins. in July or August, when they break into a branched head of clear rosy purple blossoms. This excellent plant is to the late summer garden what *S. ternatum* is to spring.

Much after the same style as the last mentioned is *S. Nevii*, another hardy American species whose little grey-green rosettes put up 3 in. stems which terminate in a branching cyme of silvery white in July. This is a first-rate dwarf *Sedum* for associating with other little things, and a still smaller species which flowers at the same time is *S. brevifolium*. This is a delightful plantling with rather blunt little stems closely clustered with nearly globular leaves arranged in rows of four. This foliage, if so it may be termed, is very mealy at most seasons, but deeply tinged with red at the time the loose sprays of sparkling white flowers appear. Even more diminutive, being only about 1 in. in height, is a form of the above known as *S. b. Pottsi*. This is one of the choicest of all the smaller *Sedums*, its mealy leaves and stems

becoming almost an electric blue during winter and spring. It is, moreover, quite hardy in the really dry chunks of a sun baked rock, to which it will cling with the tenacity of a lichen.

Allied to the above is the well known *S. dasyphyllum*, whose glaucous, rose-tinted, pebbly-looking clusters are now being hidden beneath its starry blossoms, and another even more prostrate and spreading species is *S. compactum*. The closely packed, very small rosettes of this latter are a greyish green, often turning to a deep crimson in full summer, at which season the short flower-stems produce their flat crowns of blossom which, though not particularly attractive, have one unusual feature, which is a fragrance like that of Elder blossom. The only other *Sedum* known to me which has scented flowers is a new Tibetan species, still unnamed, and which also blooms in July. In its blue-grey leafage this plant bears no little resemblance to the reflexum type, but the foliage is produced in short, flat rosettes rather than in long, cylindrical branches, and the golden yellow blossoms, with their sweet, honey-like odour, are bunched in a rounded cluster at the tips of 8 in. stems.

S. amplexicaule is interesting at this season, for having completed its year's work and disposed of the last of its large, yellow, starry flowers it enwraps its lovely foliage of cool emerald in an envelope of hay-coloured sheathes and, thus protected against sun and drought, comfortably extinguishes itself until the autumn rains reawaken it to life. Though it is said to grow larger with some, *S. amplexicaule* is very small and quite prostrate with us, and does not cover more than a few square inches, its wee branches rooting at intervals as they proceed.

Just when the various forms of *S. spatulifolium* are yielding up their summer beauty *S. multiceps* opens its lemon yellow stars, which are borne in a three-parted head supported by a stem that is shaggy with withered leaflets. The sparse foliage of this species is of the linear-leaved type, slightly glaucous and, though a native of Algeria, the plant appears to be quite hardy. Soon after this rather unkempt individual has ceased flowering the ruddy foliage of *S. oreganum* (*obtusatum*) begins to assume the rich crimson which affords so striking a combination with the brilliant golden flowers, and the increasing leafage of *SS. Ewersii* and *Sieboldii*, both very late bloomers, is developing that soft dove colour which is such an attractive feature of these plants.

If *S. spurium* (*stoloniferum*) were not so common and easy it would be deemed one of the choicest of the late summer species, for its large and abundant flower clusters are singularly beautiful, whether these are a pure silvery white, bluish pink or brilliant blood crimson, as in the variety called *splendens*. A.

OBITUARY

THE PASSING OF A COLLEAGUE.

IT is with deepest regret we record the death of Mr. W. A. Butterworth, who was for many years head of the Composing Department at this office. Mr. Butterworth was taken suddenly ill in the early hours of Saturday morning, July 14, and died almost immediately. He may thus almost literally be said to have died in harness, for until the evening before he was taken ill he went about his duties in connexion with THE GARDEN in the cheery and energetic manner which endeared him to all who came into contact with him. He was carried to his resting place at Forest Hill Cemetery by the Managing Directors of *Country Life*, Limited, and four of his colleagues, the whole staff being present.

Syringa Julianæ is a twentieth century introduction of Wilson from Western China. Although it has not the splendour of the common *Lilac* group, nor rivals even the Persian *Lilac* in beauty, it flowers freely in May and June and it has also the characteristic and delightful fragrance of its race. The flowers are nearly white on the upper side, but beneath they are deep lilac, while the calyx is violet-coloured—a striking contrast. The leaves are velvety with down beneath. It commences to flower at 1 foot 6 inches to 2 feet high, and will not, we should say, grow more than 4 feet, or at any rate 6 feet, high. It is a pretty and distinct *Lilac* and is related to *S. pubescens* and *S. Velutina*.

A Beautiful Scabious.—The Caucasian *Scabious* is not only one of our choicest border plants, regarded from the point of view of colour and form, but it is a perennial, tolerably permanent in any medium to light, well drained soil, and its flowering season often extends from May to November. Quite the most beautiful of the taller species, *S. caucasica* makes bold tufts of elegant foliage above which ascend to some 2 ft. the erect, yet graceful flower-stems, each terminating in a blossom of singular charm. These wonderful flowers, which escape the prim and buttony compactness of older types of this genus, are often 3 ins. in diameter and range in colour from pure white through cool lavender to a clear flaxen blue. Though not a difficult plant under the above-mentioned conditions and given full exposure, *S. caucasica* dislikes excessive wet and should not be overhung or crowded up with other things, especially in winter. Some old mortar may be put in with the roots when planting, and an occasional top-dressing of lime is appreciated. Propagation is carried out by seed, which ripens and germinates freely. In districts where *S. caucasica* is unreliable it may be treated as a biennial.

Chionanthus retusus (the Chinese Fringe Tree) was first introduced by Fortune from China in 1845, but it did not, apparently, then survive, and it was not until Messrs. Veitch's collector Maries sent it home nearly forty years later that it became established in gardens. Even now it is very uncommon. Of the "Fringe Trees," only two species are known, the other being the well-known *C. virginica* of the United States. They afford one of several instances of the remarkable isolation of one species in North-Eastern Asia, while its only fellow is in Eastern North America; other examples may be cited in the two *Tulip* Trees, the two *Yellow-woods*, and the two species of *Sassafras*. Alike in their snowy white, narrow-petalled blossoms, the Fringe Trees are distinct in their manner of bearing them. It will be found that *C. retusa* carries them in clusters at the end of short, leafy twigs of the current year; but in *C. virginica* they are borne in a dense mop-like mass at the end of the previous year's growth, and below the young shoots of the current year. *C. retusa* needs, above all, abundant sunshine; if the planter gives it his sunniest spot and a sound loamy soil to grow in, he has done the best he can for it. The finest plants we have seen are in one of the city parks of Rochester, N.Y.

Roses and Carnations at Harrogate.—Under the auspices of the North of England Horticultural Society and the British Carnation Society, a joint exhibition will be held in the Winter Gardens, Harrogate, on August 22, 23 and 24. Schedules may be obtained from either of the Secretaries, Rev. J. Bernard Hall, Farnham Vicarage, Knaresborough, or Mr. P. L. Bunyard, 57, Kidderminster Road, Croydon.

ALLWOOD'S PATENT PLANT SUPPORT.

One of the greatest labour saving devices in horticulture. It is placed in position in less time than it takes to tie a plant with stakes and raffia. *Perfectly Simple.*

Hawker & Botwood Ltd., Grays, Essex
SAFETY FIRST

It's the same with Paint.

THERE'S many a soap that, after a fashion, will cleanse your hands of grit and grease; but most of them jib at paint.

Kit is absolutely in its element with a job like paint or varnish or tar. Just a little water, an easy rub-rub-rub, and in a trice the hands are clean.

Kit is a Speed Soap from the word "Go!" The tin is easy to pack and pull out again, and the special lid lifts off at once. And, if you're in a tearing hurry, you can easily use it without water!

6d PER TIN.

LILIES IN THE GARDEN

BEFORE proceeding any farther it may be as well to issue a warning that the following notes are intended primarily for garden-lovers who have hitherto not had experience in the cultivation of Lilies in the garden. Much of the information is as old as the genus Lily is to cultivation, but it is a noticeable fact that during recent years very little practical information has appeared in the gardening Press on the elements of success in the culture of Lilies generally. Novelties have been described, new introductions from China and elsewhere, and varieties—meritorious and otherwise—produced by hybridists, have been discussed; but regarding the practical necessities of the culture of the genus little has been published. Since the period when *THE GARDEN* and most other periodicals were publishing frequent notes on the best methods of growing the various species a new generation of garden-lovers has grown up. This must be my excuse for going over very old ground and for saying things that are common knowledge among those who have been growing Lilies for many years.

I think this is what the Editor had in mind when he wrote me asking for a "practical" article on Lilies. He was just off for his holiday and, with a sublimely brutal indifference to the fact that I was trying to snatch one myself, despatched a request couched in irresistible terms that reached me (after being readdressed several times) a day after he wanted the copy in the office. The moment of its arrival was inopportune. How can one be practical lying on a couch of wild Thyme mingled with dainty grasses and surrounded by myriad blooms of wild Centaury? Below me stretched acres of Sea Pinks, now mostly brown, but still bright with thousands of belated blossoms, and all around them masses of Teasels, Sea Holly, Mallows aglow with silvery pink, and here and there patches of Sea Lavender many yards square in full flower. Beyond, a stretch of foreshore

green with new seaweed stirred at its farthest edge by the lazy ripple of the surf. I thought there was not another human being within a mile, when suddenly there descended on me this request to be "practical."

In any case it is difficult to be altogether practical when writing of Lilies. If chiselled marble is, as it has been called, "frozen poetry," then Lilies are among other flowers of the garden living poems. They have inspired more poetry and provided more poetic symbols than any other flower, and in them the extravagance of language

of all the poets, both Eastern and Western, has found its culmination. But I think "practical" was the word the Editor used.

Some years ago I was visiting a garden in which nearly everything that art, science and wealth can achieve had been attempted. There were many notable successes therein, but one just as notable a failure. This was in what was called a Lily garden. It consisted of a broad level area, solidly paved, into which a geometrical design of beds had been worked, and planted with Lilies of every variety obtainable, and Lilies only.

How anyone with any knowledge of the genus and its cultural requirements could have expected success under such conditions it is impossible to conceive. Out in the blazing sunshine there were several thousands of the best known Lilies, all being given exactly the same treatment, unprotected, and unsupported by any other vegetation. This in itself was wrong and sufficient to ensure failure. The various species require different treatment and conditions of cultivation, and Nature has forbidden them to respond satisfactorily to such arbitrary and communistic cultural regulations. What is more, there are few of them that enjoy full sunshine or dry heat, and even that few demand the protection of shade to the roots. Another objection to planting Lilies under such conditions lies in the fact that the broad stone paths not only act as heat reflectors, and so make the exposure worse, but are quite incongruous in association with 90 per cent. of the genus, and unnecessary for the remainder.

Possibly, half the recorded failures in the growing of Lilies are due to the fact that insufficient attention is paid to the cultural requirements of the particular species. Yet they are in all cases simple enough and, given the facilities of any ordinary garden, properly applied, the achievement of success presents no difficulty greater than that of most other garden plants. In every department of garden activity it is found

THE NANKEEN LILY, *LILIUM TESTACUM*.

AN EXCELLENT LILY FOR A SHADY BORDER, *L. MARTAGON* ALBUM.

that certain varieties succeed better under certain conditions than others. Even Potatoes have their preferences in this respect, and nearly every gardener knows of one or more varieties of Roses that succeeds well in other gardens but which he has never been able to grow. It would probably be difficult to change the soil conditions of the kitchen garden to such an extent that the unsuccessful Potato can be grown. It is a simple matter to apply corrective treatment to the small area required to grow any particular Lily. As a matter of fact, the soil variations in any garden or, indeed, in all the gardens in Great Britain can be summarised under a very few descriptions :

1. Damp, cool soils that are permanently moist, such as are found on low-lying land, by the sides of natural streams, ponds and other waterways.
2. Cool, rich loam that in agriculture is described as good corn land.
3. Light, dry soils mingled with sand or gravel that drain freely.
4. Peaty soils that may be moist and cool, and which offer a free open root-run, or may be mingled with sand and therefore drain quickly and are, consequently, drier.
5. Heavy clay soils that stick like glue when wet and bake like bricks when dry.

*LILIUM SARGENTII* AMONG AZALEAS.

With regard to the first four, there are Lilies that will succeed admirably with the most ordinary amount of cultivation ; but with the last, nothing but the most liberal treatment will produce satisfactory results with Lilies or anything else. It must not be assumed, however, that any one of these soils is suitable for all Lilies. It would be folly, for instance, to plant *Thunbergianum* Orange Queen or the beautiful forms of *L. speciosum* in the permanently damp soils described in No. 1 above. This is the place for *Lilium pardalinum* and its varieties, for *L. canadense*, *L. superbum* and, indeed, all the North American Bog Lilies. Here they will revel and increase and, even if planted by the waterside, thoroughly enjoy themselves, because they like the moisture. There is, perhaps, no waterside planting more enchanting than a group of *Lilium pardalinum* towering above the cool green foliage of *Epinedium*, or some of the moisture-loving Ferns, or, perchance, one of the dwarfier *Spiraeas* or *Astilbes*. Its richly coloured orange and crimson flowers give one of the most vivid colour notes obtainable in such a position, and when the rippled surface of the water reflects the glow in a mingled wash of crimson, gold and orange it has all the glory of a sunset in miniature. Nevertheless, although it loves the moisture, it is a very accommodating variety, and is not so insistent upon it that it will not flourish in the garden where the soil more nearly resembles that described under Nos. 2 and 4 above ; in fact, where the soil is good and not too dry it makes an excellent border plant.

For the cool rich loam described under No. 2 some of the most suitable species are the *Tigrinum*s—of which *Fortunei giganteum* is by far the best—the *Auratum*s and all the *Martagon*s. The latter are, perhaps, the least particular of all as regards the soil in which they will do well. In planting in such soils care must be taken to dig deeply, ensure thorough drainage, and assist root action by rendering the soil as open and free as may be, by the addition of a little peat if possible, but, certainly, a quantity of decayed leaf-soil and sharp sand.

In the light soil described under No. 4 the largest group that will succeed, and the one that offers the most attractive varieties for garden culture, is the *speciosum* group and its kindred, most of which are late summer flowering ; but for earlier effects the *umbellatum* and *elegans* (or *Thunbergianum*) varieties are equally happy. *Lilium elegans* Orange Queen is deservedly the most popular of these, but the colour is better described as rich apricot rather than orange. *Lilium longiflorum*, the magnificent white Trumpet Lily, and its relations *L.L. candidum*, the old white Madonna Lily, and *crocinum*, the Orange Lily, will do equally well in such soil, and also, with a little encouragement in the way of lightening and opening, in No. 2.

The peaty soils described under No. 4 can be made to grow practically every Lily suitable for out-of-doors cultivation. For such as require a stiffer, richer medium it is easy to add a quantity of chopped fibrous loam, such as the top spit of an old meadow thoroughly decayed and free from wireworm. For those that prefer lighter conditions the addition of manure not too fresh, leaf-mould and, if sand is deficient, some light gritty material (but not of a limy nature) is all that is required. In the heavy clay soils described under No. 5 nothing can be done except digging out the area it is desired to plant a couple of feet or so deep and filling it up with a compost suitable for the particular section of Lilies chosen to grow, first taking care well to break up the bottom of the hole and work in any rough material that will ensure good drainage.

So much for the soils that will of their own accord or can be made to grow Lilies. The next

point is the sort of position that is suitable for them and which they will enjoy. This, again, is entirely dependent upon the variety, or perhaps

(To be continued.)

it would be wiser to say that the variety should be chosen according to the position to be planted.

GEO. DILLISTONE.

THE BULB ORDER

I.—Bulbs for Pots.

HOUSE only, or greenhouse? It makes a difference if one has to do all one's growing in a dwelling-house without perhaps even the help of a cold frame, and if one has a greenhouse and the usual appurtenances thereof. I divide my remarks accordingly.

Where all has to be done in the house and where the windows are the only "greenhouses" available, the wisdom of the wise consists in growing just the bulbs that are most likely to do well and no others. Much will depend upon the care and attention which the grower gives them. Week in, week out, it must never be relaxed if such potfuls of flowers are to be produced as those which I once saw in the window of a neighbouring vicarage or as the Freesias which Mr. John Bain enjoyed in his cottage home in North Scotland after his retirement from active service.

Although this is not an article on culture, I feel I must give one little bit of advice which it is well to follow, especially if the much advertised drainless bowls are used instead of ordinary flower-pots. It is, not to be in too great a hurry in potting. Towards the end of October is about the right time for the operation. Roots are then sooner formed than if the bulbs had been planted earlier, and the foliage when it appears has not so long to grow and get leggy before the flowers come. The order I would give if I had only a house to do my winter gardening in would be something like this: Roman Hyacinths; Paper-White Narcissus, Henry Irving and Golden Spur Daffodils; Scarlet Duc Van Thol Tulips; Vermilion Brilliant and Prince of Austria Tulips, Murillo double white and blush Tulips, and the following Hyacinths: L'Innocence (white), Garibaldi (red), Schotel (pale blue) and Lady Derby (pink). After many years' observation I have come to the conclusion that no bulbs are so easy to grow indoors from the start to the finish as Dutch Hyacinths. It has been remarked that any fool can grow them. Quite true, but it is the wise man who chooses them!

Of late years a novelty, in what are called Prepared Hyacinths, has come on the market. Advertisements announce that they may be had in bloom at Christmas. So they may if they can be given a little bottom-heat and carefully shaded during a part of their period of growth, but as bottom-heat is out of the question in rooms, no one under the conditions about which I am writing should attempt this. All the same they are worth buying, for I have found that under exactly the same conditions as ordinary Hyacinths they flower from a week to ten days in advance.

The last part of this article is intended for those who have greenhouse accommodation, and if they also have cold frames from which frost can be kept out, all the better. First let me give a word of caution before suggesting a purchase of Prepared Hyacinths. They may be "flowered" at Christmas-time as the photograph of a bulb show at Haarlem last Christmas shews us (THE GARDEN, February 10, 1923, p. 71), but it is a ticklish job to accomplish successfully; all the same, it is worth trying, for the bait is very tempting. I have never managed it myself, as I have not enough heat and no convenience at all for

bottom-heat, which I am told they require. Bulbs should be got as soon as possible and *at once* potted and plunged so as to get plenty of roots before November, when the forcing process must be started. It would be very kind if someone who has done it would tell us all the details of their management. The four to which I would pin my faith would be L'Innocence (white), Lady Derby (rosy pink), Schotel (light blue) and Garibaldi (carmine). These are my stand-bys. Among the

orange sport from that splendid fellow Prince of Austria. These are both single varieties. To them I would add Safrano or Tea Rose. I am surprised to find typical lists like those of Dobbie and Sutton without it. Among Darwin Tulips a good half-dozen for pots are Pride of Haarlem, William Pitt, William Copland, Bartigou, Baronne de la Tonnaye and Suzon. Cottage varieties as a rule do not lend themselves to pot culture. For late flowering I can recommend Inglescombe Pink and John Ruskin, also the following, which in some lists are classified as Breeders and in others as Cottage: Golden Bronze, Bronze Queen, Dom Pedro and Goudvink. As with Tulips so with Daffodils, there are a great many which may be used for growing in pots. It is very much a question of taste. With the exception of the deep coffee-coloured Dom Pedro I have not put down any very dark variety, not because I do not like them, but because in the early months of the year we want brightening up.

Among Daffodils nothing is so effective as King Alfred or, if a paler yellow is preferred, Olympia, but many must be content with the lower-priced Golden Spur and Emperor. Just so in the so-called white trumpets one would like Mrs. Ernst H. Krelage, but our pocket forbids anything more expensive than Mme. de Graaff, or in the bicolors we wish to have Weardale Perfection or Duke of Bedford, but only Victoria and Mme. Plomp are practical politics. For small pots W. P. Milner is excellent. In a little heat it comes almost white. No one should omit two or three red-cupped or red-rimmed varieties. The colour does not burn so soon as it does out of doors, and we can enjoy their beauty for a longer space. Blackwell, Lucifer, Firebrand, Albattross, Acme, Homer, Red Beacon and, above all, Lady Moore are examples of what I mean. If bunch-flowered Daffodils are wanted, few excel Admiration, Orange Cup and Orange Blossom.

LARGE-FLOWERED PAPER-WHITE NARCISSUS.

others that I like best are De Wet (deep blush), Jacques (immense spike, pink), Captain Boyton (blue), Johan (lavender), Oranje Boven (ruddy apricot, spike like a Roman Hyacinth) and Chestnut Flower (deep blush, semi-double, very beautiful). Laura I grew for the first time last season. It is a rather pale rosy mauve with a medium-sized spike. Honestly, I do not know whether I like it or not. It is certainly something out of the ordinary run. Unless I were about to exhibit I would never buy first or top-sized bulbs. Second-sized and Cyntellas are quite good enough for ordinary people. These last are full of grace and charm as, indeed, all young things are. Cyntellas are but three year old bulbs of what we know as first-size Dutch Hyacinths.

Passing on to Tulips. Why not try Jenny, a pretty rose and one of the sweetest scented of all Tulips; and General de Wet, or, as it is now usually called, de Wet? This is a glorious

Nature has marked out Daffodils, Tulips and Hyacinths as the "big three" among spring-flowering bulbs in pots, but there are other families of lesser importance which must not be overlooked. Freesias, white and coloured, make a pleasant change. Among these last Apogee and Yellow Queen for yellows, and Dainty, Conquest, Apotheose and Mouette among the other shades are those to which I would give a trial. If a Crocus be wanted, why not the little rosy mauve Sieberi? or if a dwarf Iris, why not reticulata? Why not try one or two pots of Lachenalia Nelsoni, or the white Fritillaria Meleagris, or the effective Babiana stricta rubro-cyanea—the Babiana *par excellence* with its striking flowers of soft blue with a glorious bright carmine centre? and lastly, what about Ixias if you have sufficient space to give them in a cool frost-proof frame or greenhouse before they bloom in June? What must they be like when they can be grown in the open? JOSEPH JACOB.

THE MOCK ORANGES

A group of hardy flowering shrubs which blossom during June and July the genus *Philadelphus* is one of the best known and most valued. No exception need be taken to the fact that nearly all have white flowers, for these are produced in profusion, and many are deliciously fragrant. Flowering in company with the Spanish Broom (*Spartium junceum*) and the Mount Etna Broom (*Genista tinensis*) we get a delightful contrast and feast of colour about mid-summer in the pleasure grounds and shrubbery borders.

The Mock Oranges are natives of three continents, being found in South-Eastern Europe, North America, the Himalayas, China and Japan, with *P. mexicanus*, as the name suggests, a native of Mexico.

The collection of *Philadelphuses* at Kew contains about thirty species, a number of distinct varieties, and a fairly wide selection of hybrids. While a

P. is about the year 1881 that *M. Lemoine* produced *P. Lemoinei*, which is the result of crossing the Rocky Mountain *P. microphyllus* with pollen of the European *P. coronarius*. Since that date almost if not quite yearly additions have been made to our gardens. Some are dwarf and bushy in habit, others rather taller and open in growth, all notable for the freedom with which the single, semi-double or double blossoms are produced. In recommending a selection of varieties it is difficult to limit the number to a dozen when it is remembered that at least six of *Lemoine's* hybrids have received awards of merit and one the first-class certificate of the Royal Horticultural Society. *Argentine*, double, lasts well in flower; *Boule d'Argent*, very free, double; *Bonquet Blanc*, dense clusters of semi-double flowers; *Dame Blanche*, creamy white, semi-double, very fragrant and erect in habit; *Fantaisie*, large single blossoms with a rose-tinted

calyx and branches carrying quantities of blossoms during the second half of June. *P. Gordonianus*, from the Western United States, is more upright in growth and has slightly larger flowers. Other American species include *P. grandiflorus*, which is notable for its large pure white flowers 2ins. across, borne on vigorous bushes up to 12ft. or 15ft. high, and *P. latifolius*, which makes an even taller bush with slightly smaller individual blossoms but more in a cluster than the last named.

The Common Mock Orange, *P. coronarius*, is one of the earliest to flower and a popular shrub in very many gardens. It is a native of South-East Europe and Asia Minor. Cultivated in Britain in the sixteenth century.

Among the Chinese species *P. Magdalene* is a fine bush with arching stems, darkish green leaves and panicles of pure white flowers about 1in. across. *P. purpurascens* is one of Mr. E. H. Wilson's introductions. The name refers to the calyx clasping the cupped pure white flowers, which are pleasingly fragrant. Though not such

VOIE LACTEE.

PURPUREO-MACULATUS.
THREE BEAUTIFUL MOCK ORANGES.

VIRGINAL.

few of the species are very distinct, others are not easy to distinguish, the more so because natural hybrids occur to still further complicate matters. It is not surprising to find the hybridist taking full advantage of the ease with which the species cross-pollinate.

The first hybrid of which there appears to be any definite record is *P. insignis*, raised in France over fifty years ago by M. Billiard, of which *P. grandiflorus* is said to be one of the parents. Other names by which it is known are *P. Billiardii* and *Souvenir de Billiard*. This hybrid should be in every collection, for it is not only one of the best to flower, but it is one of the most beautiful of the tall-growing section with snow white cupped flowers freely borne in lengthy clusters.

The present-day race of Mock Oranges is almost, if not entirely, due to the efforts of one man, M. Lemoine of Nancy, and the fact that his first hybrid bears the raiser's name will ensure its association for many years with the beautiful race of summer-flowering shrubs he created

centre; *Gerbe de Neige*, large fragrant single blossoms; *Mont Blanc*, free flowering, pure white. *Norma*, the long, slender branches, gracefully arching, are clothed with large flowers; *Purpureo-maculatus*, the white flowers have large purplish rose centres; *Ruge-rose*, another pretty bush with purplish centred blossoms; *Virginal*, the best double white sort, the large flowers are pleasingly fragrant; *Voie Lactée*, a large single sort with snow white blossoms.

Among the species best deserving a place in every garden is the Rocky Mountain *P. microphyllus*, to me the most powerfully fragrant of all the Mock Oranges. It is a close-growing bush up to 2ft. to 3ft. high and more in diameter, the long, slender branches full of small white blossoms interspersed among the small foliage.

P. Lewisii, a native of Western North America, has been cultivated in our gardens for a hundred years. It is among the most valuable of the tall species, forming large masses 10ft. or 12ft. high and as much or more in diameter, the

attractive garden shrubs, *P. brachbotrys* and *P. pekinensis*, both from China, are noteworthy because of their pale yellow blossoms. *P. Falconeri* is presumed to be a native of Japan. It is one of the tallest-growing bushes and readily distinguished when in flower because of its long narrow petals.

The best known of all M. Lemoine's hybrids is *P. Lemoinei erectus*. For lawn beds it is one of the most valued hardy shrubs, producing in June masses of small fragrant white blossoms.

There are very many places for the *Philadelphuses* in our gardens and pleasure grounds. To ensure the ripening of the wood, without which flowering will be sparse, plant mostly in sunny positions. The tall-growing bushes should find a place at the back of shrubbery borders and in the pleasure grounds group planting is very effective. For a large lawn bed *P. Lewisii* is particularly attractive. The newer *Lemoine* hybrids, such as *Virginal* and *Voie Lactée*, are wonderfully showy for lawn beds, massed in the foreground of shrubberies, and on sloping banks, it may be on the borderland

between the pleasure grounds proper, and the woodland.

Another use for the Lemoine hybrid Mock Oranges is to lift and flower in pots, gently forcing the plants into bloom for the conservatory or cold greenhouse. For this purpose they are quite as easy to manage as *Deutzia gracilis*, its varieties and hybrids.

CULTURE.—The Mock Oranges thrive in most cultivated garden soils. Trenching and manuring of the ground are desirable, for in this way the plants make vigorous young growths, which are the prelude to an abundance of blossoms the following year. After flowering each year a certain amount of pruning and thinning of the growths is desirable, otherwise the bushes eventually become a tangled mass of twigs giving only small flowers. By removing the branches or twigs

which have flowered, the energy of the plants is thus centred in the development of new growth.

In some varieties, notably *Lemoinei erectus*, it is worth while cutting out all the old flowering wood which can be spared to the ground. After the second or third year stools are formed and an abundance of vigorous shoots push up annually from the base. A liberal mulching of decayed manure to coincide with the pruning is very beneficial.

The *Philadelphuses* are readily and rapidly increased by cuttings made of the young shoots from July to September. The earlier growths root best in a close frame with slight bottom-heat. From the middle of August onwards a cold frame kept close or a hand-light on a west border will suffice. A. O.

FLOWERING SHRUBS IN A WEST COUNTRY GARDEN

IF we set aside the *Cistuses* and *Brooms*, a considerable share of the remaining responsibility for the "furnishing" of one's July-August garden falls to the later members of the genus *Spiræa* and *Philadelphus*. In regard to the former the lower levels of a partially shaded glade which is blest by the kindly ministrations of a brook provides the coolness which so many of the *Spiræas* enjoy, while the higher, more sunny slopes are what the others like best.

One of the prettiest and most distinct of the shrubby *Spiræas* is *S. (Neillia) opulifolia aurea*. Though the type species of this variety attains almost the dimensions of a tree, the above form is a medium-sized shrub whose primary charm is the golden colour of the broad-lobed, hop-like leaves. The blossoms, which appear in little fuzzy clusters of white on the upper sides of the spreading branches, are of secondary importance.

Then we have several species which may be considered collectively owing to the general similarity of their more or less ruddy stems, long and handsome pinnate leaves and terminal panicles of flossy inflorescence. *S. Lindleyana* is one of these, an extremely elegant shrub of 6ft. to 10ft. in height, which should not be omitted from the smallest collection, and near to this comes the rather more stiffly branched *S. Aitchisoni*, with redder bark, long ash-like leaves and the same drooping, creamy white flower clusters. The former being a native of the Himalayas and the latter of Afghanistan, a fairly warm, yet tolerably moist soil appears to be the most desirable, *Lindleyana* having a reputation for being the more fastidious of the two. *S. sorbifolia*, a European species which flowers rather earlier is also of the above description, but of it we have had no personal experience. *S. discolor (ariæfolia)*, a shrub of singular beauty and reliability, may also be included in this group.

The finest *Spiræa* of the ash-leaved set, however, and one that is destined to prove itself to be one of the most magnificent shrubs of recent introduction, is *Spiræa (Sorbaria) arborea*. We are indebted to Mr. E. H. Wilson for this noble species. He brought it from China a few years ago, and all reports which have thus far come to hand regarding it testify to its splendid vigour and incomparable beauty. Since *S. arborea* will go up to 20ft. and send out its great arching wands on all sides with a fern-like grace, it needs ample space. Here, we have only a few young specimens no more than a yard or so in height; but already the beautiful pinnate leaves, like those of *Ailanthus*

glandulosa, with their fresh apple green and wine red stems, are very large and singularly graceful. The plants promise to fulfil all that

THE BEST OF THE SHRUBBY SPIRÆAS, *S. LINDLEYANA*.

the few who know this shrub have to say of its excellent qualities, and even such youngsters as these are making preparations for embellishing the extremities of their elegant growths with those enormous plumes of creamy white inflorescence with which *S. arborea* is adorned throughout August and September.

And so to *Philadelphus*, the highest award of merit among which must still be bestowed upon *P. Virginal*. That, at any rate, is my own feeling about it, for there is a quality, a flavour of good breeding about the very large white (really white) blossoms of *P. Virginal* which, against the dull, cucumber green of the ample foliage, affords this variety a distinction not shared by any other of the group. *P. Virginal* is, moreover, a robust grower, going up to 6ft. and more, and if its immaculate blossoms, borne in July, have no more than an extremely delicate fragrance, this will not be counted as a failing by those who know *P. coronarius* and a few other kinds too well.

P. Vire Lactée, rather earlier than the above, is perhaps the best of the single whites of medium stature (3ft.). The foliage of this variety is also

a good dark green, and the large, milk white blossoms are of extraordinary texture and very lovely with their central tufts of golden stamens. *P. grandiflorus* is probably the best of the taller species, and one that bears no little resemblance to *coronarius*. But its much larger, almost scentless flowers are whiter than those of the latter, they come later, and the bush is generally taller and more vigorous. There are, however, several forms of this American Mock Orange, some of them being named (*floribundus*, *laxus* and *inodorus*), and it is probably on that account that one experiences some difficulty in securing a fairly representative specimen.

Many of the Lemoine hybrid *Philadelphuses* are first-rate varieties, dwarf and tall, which will often carry bloom from June to August, and several growing here are very content in our light woodland loan wherever they can get some share of the sun. Most of these hybrids have their origin in *PP. microphyllus* and *coronarius*, the former being a delightful shrublet with a tangle of thin, wiry stems which gives us in July a starry galaxy of little milk white blossoms whose delicious scent has not the sickly sweetness of the more familiar Mock Orange.

Though *P. mexicanus* is too tender for all but very favoured districts, it has handed on to one

of its offspring (*P. Coulteri* being the other parent), the purple-blotched *P. purpureo-maculatus*, its spicy aroma curiously suggestive of some scented soap. This is an extremely prolific bloomer in warm, poor soil, and since its introduction we have had several others with the base of the petals blotched or shaded with various tones of purple and pinky red.

Grey-leaved shrubs are generally attractive, but never more so than in the dog days and when growing on those shallow slopes whose reserves of moisture are as precious as they are poor. One of the handsomest of these now in flower is *Senecio laxifolia*, whose large, many-branched heads each bearing a crop of boldly rayed flowers, like golden yellow *Cinerarias*, make a more satisfying display than one usually gets in the Groundsel breed. The neatly rounded leaves are, moreover, extremely woolly and white, and the shrub is generally more attractive than *S. Grayii*. The old *Santolina incana* is not to be despised for banks and slopes that are arid enough to try the courage of Catmint and *Artemisia*, *Marrubium* and Sage and other fragrant heat lovers of the

kind. The innumerable *Helichrysum lithospermum* is, however, whiter than any of these, perhaps the whitest thing in the garden to-day, and it is certainly no less drought proof. It makes a loose-habited little bush of 15 ins. or so in height, with tough and narrow leaves without a trace of green, and above these rise to a foot or more a number of equally white flower-stems which terminate during the later summer in bunchy heads of clear yellow.

A refreshing object to look upon when our little valley is a sun-trap and the Broom pools are snapping like the crackling of a bush fire is *Feurium fruticosum*, delightfully cool in the silvery freshness of leaf and stem no less than in the pale sheeny azure of its large and pretty blossoms. This is a thin-habited, somewhat straggling shrub which varies considerably in stature in accordance with situation and climate. It grows to about 4 ft. in the open here, where it is hardy enough to stand without protection. On occasions when it has been injured by frost it has broken freely

from the base in spring. Though it has not yet stood a real test for hardiness, *Sutherlandia frutescens* promises favourably. This is a shrub of outstanding beauty, its stems and delicate mimosa-like leaves being a silver grey, while the lobster-claw flowers are a vivid orange-scarlet which glows into vermillion at the tip.

The *Oleas*, which are closely allied to the *Senecios*, also come into one's grey list, and one of the best of the hardier kinds is *O. macrodonta*, which adorns its holly-like branches with copious clusters of fragrant, daisy-like flowers during this month and next. This is not quite as hardy as *O. Haastii*, yet much more reliable than *O. semidentata*, which is the pick of the bunch with flowers like rosy lavender *Marguerites*. The said *Haastii*, though widely planted by some, is one of the few shrubs one could almost despise. So it was expunged years ago from this garden to make way for choicer and less dismal things and flaming swords do sentry-go over the garden gate.

Jasminum humile revolutum is a hearty, beautiful shrub that would doubtless be more generally grown were it not for its reputed tenderness. Here, it is as hardy as a *Laurustinus*, and it can be relied upon to flower with unfailing regularity every July. Though the blossoms, borne in ample clusters, are scentless, or nearly so, their rich yellow is very attractive against the dark bay green foliage. The pink twining *Jasmine*, *Jasminum Beesianum*, introduced by Messrs. Bees, Limited, a few years ago, has grown with commendable vigour, covering a stump some 10 ft. high, but as its stature has increased so have the flowers grown smaller. In a year or two at most they will have shrunk to vanishing point, and one wonders whether this Chinaman demands frequent uplitting and renewal. The familiar *Jasminum officinale*, unfortunately, seems to grow scarcer year by year. Does anyone ever plant it in these days or the large-flowered form known as *J. o. affine*? The fine old double-flowered variety is still more rare. NORTH WALES.

SUMMER FLOWERS AT VINCENT SQUARE

THERE was a pleasant variety of flowers at the Royal Horticultural Society's Hall, Westminster, on July 24, and the exhibits were decidedly more numerous than might have been expected at the time of the year, especially considering the unfavourable weather. Just inside the entrance the Donard Nursery Company set up a very uncommon exhibit of *Dierana* (*Sparaxis*) *pulcher-*

rimum and its varieties. The tall, arching plumes of flowers, which retain their spathes, presented quite a foreign appearance and intrigued many visitors. Besides the new variety *Heron*, which is described under "New and Rare Plants," they shewed *Osprey* and *alba*. The former is very attractive, but the latter would not fascinate alone, yet is valuable in association with the others.

Along the back wall by the gallery stairs there was an exhibit which, in the opinion of ourselves and also of many visitors, was well worthy of a gold medal. There was, perhaps, a slight formality in the arrangement of the water lily pool—even this would be a matter of personal taste—but there could be no two opinions as to the immense value of the many *Nymphæas* which were so successfully disposed in the water. As we know full well

THE CURIOUS ARISTOLOCHIA GIGANTEA.

DIANTHUS HERBERTII MRS. GIFFARD WOOLLEY.

from experience, it is no easy matter to exhibit Water Lilies in anything approaching naturalness, but in Major Albert Pam's pool his gardener (Mr. F. Streeter) was particularly successful. Among the many varieties there were Conqueror, Newton, Galatee, Wm. Doogue, Escarboucle and James Brydon. The pool was framed with tall, graceful Bamboos and elegant Grasses.

In the centre of the hall Messrs. L. R. Russell, Limited, arranged what must have been a "near-gold" medal group of splendidly grown *Nepenthes*, *Caladiums*, *Alocacias*, *Marantas*, *Thunbergia grandiflora*, *Ixoras* and other tropical plants. On behalf of Mr. T. A. Bull of Hill Top, Norwood, Mr. W. R. Portall staged a highly creditable collection of *Gloxinias*.

The great variety of "Scented Geraniums" which may be grown was well illustrated by a large collection from the gardens of the Hon. Vicary Gibbs at Aldenham, and among them was *Pelargonium tetragonum*, which in its erect, fleshy stems had more the appearance of a succulent plant. As a rule one does not associate flowers with these aromatic species and varieties, but quite a goodly number are worth growing for their blooms. Among such are *Clorinda*, *Zermattii*, *Miss Godolphin*, *Osborne*, *Prince of Orange*, *Crimson Unique* and *Scarlet Unique*.

Herbaceous *Phloxes* were in such quantity as to shew that it is quite midsummer in the garden, and this was more than borne out by the numbers of *Gladioli* spikes on view. The largest exhibitor of the *Phlox* was Mr. H. J. Jones, who made an imposing display. Although it was a hot day, yet it seemed to be the brightest colours that received most attention, and these included *Jessie Waters*, *Homeland*, *Coquelicot* and Dr. Koningshofer.

Many *Gladioli* were displayed by Messrs. Kelway and Son, and besides the elegant *Primulinus* hybrids they had many of the larger-flowered sorts. Messrs. Lowe and Gibson shewed some good forms of the *Primulinus* hybrids and also some excellent border *Carnations*.

Among the general border flowers there were large masses of the showy *Lavatera Olbia rosea*, the smaller flowers of *Sidalcea Rose Queen*, several *Kniphofias*, *Salvia turkestanica*, Japanese *Iris*es from the Orpington Nurseries Company and from the Donard Nurseries, the lovely blue *Belladonna Delphinium* in Mr. Carlile's corner group, and a nice variety of dwarf *Campanulas* in the collection of Messrs. R. Tucker and Sons.

A large exhibit of annual *Scabious* was set up by Messrs. Sutton and Sons, and these were in named colour varieties. Mr. C. H. Herbert had an assortment of his garden *Pinks*, chief among them being a vase of the deliciously fragrant Mrs. Giffard Woolley. This is quite as large as a *Carnation*, of bluish colour with a pale crimson lake zone. *Prince of Wales*, *Bridesmaid* and *Model* were also excellent. Messrs. Carter and Co. had a group of the old *Trachelium coeruleum* bearing large heads of the cloudy blue flowers.

There were several collections of *Roses*, but it certainly has not been a *Rose* year. Under the clock Mr. Elisha J. Hicks shewed several vases of *Dorothy Dix*, a dwarf *Polyantha* much of the type of *Ellen Poulsen*, though a trifle looser and of a bright rose pink colour. Messrs. D. Prior and Son, Limited, shewed many varieties of *Roses*, including *Vera Prior*.

The second show of the National *Carnation* Society was, like that of a fortnight earlier, quite a small affair, and it was a difficult matter to discover the requirements of the classes.

The first prize collection was by Messrs. Lowe and Gibson, and this included their new *Ivan Lowe* and, in *Eclipse*, the premier light-edged white-ground *Picotee*. The firm's new variety

Mrs. E. Charrington was the premier white-ground *Fancy Carnation*.

Miss Shiffner won many first prizes and, in what we imagine was the colour classes, she had beautiful blooms of *Opalesce* (deep old rose), Mrs. R. P. Smith (blush), Mrs. G. Marshall (crimson), Jean Douglas (scarlet), *Border Yellow* and *Purity*. Her really magnificent flower of

medal was awarded to Mr. Stoop and the bronze to Mr. Pateman for *Gooseberries*.

NEW AND RARE PLANTS.

Aristolochia gigantea.—This was quite the most uncommon flower in the Show. The distended tube is of pea green colour, and it expands into a pair of large lobes which gives the flower

THE CHINESE YELLOW WOOD, CLADRASTIS SINENSIS.

Mrs. A. Brotherston was the premier *Clove*. In one class Miss Shiffner had excellent vases of *Gordon Douglas*, *Lord Kitchener* and *Rose Clove*.

Among the few classes set out in the annexe Mr. E. Charrington was a successful exhibitor, shewing good blooms of *Eclipse* (*Picotee*), *Grey Douglas*, *Glamour* and *Veldt Fire*. The *Edmund Charrington Cup* was awarded to Mr. H. A. Knapton.

Hidden away in the *Orchid* annexe, where very few of the visitors discovered them, were the finest trained bushes of *Gooseberries* we have yet seen at any show. Mr. J. C. Allgrove is a past-master in the art of growing and training fruit trees, but with these many *Gooseberries* he has excelled himself. There were little pyramids, fan shaped and espaliers, and not only were they models of training, but all bore heavy crops of luscious-looking fruit. Besides, Mr. Allgrove staged eighty dishes of gathered fruits. The big *Gooseberries* were not quite the "Big *Gooseberries*" so beloved of the fancier in the North of England, but they were still quite big ones, and were of such sorts as *Leveller*, *Coiner*, *Matchless*, *Keepsake* and *Brooming* of the green and yellow varieties; and *Warrington*, *Whinham's Industry*, *Highlander* and *Dan's Mistake* of the red-skinned sorts. As though to draw comparison there were, in this gold medal exhibit, dishes of the smaller *Early Green Hairy*, *Ironmonger* and the superb-flavoured *Langley Gage*.

The R.H.S. sent from the Wisley Gardens a large collection of gathered *Gooseberries* in many varieties, and Messrs. Laxton Brothers shewed several baskets of a new *Strawberry* named *Omega* which the Fruit Committee did not consider superior to older sorts. They were shapely fruits with some of the dark colouring of *Waterloo*, and had travelled well. The *Bunyard silver-gilt*

a somewhat bat-like appearance. These segments are of brownish maroon colour, freely and irregularly veined with sulphur yellow. The woolly throat is pale yellow colour. The smallish, ovate leaves are a shining pale green. Unlike so many of the genus, this species is pleasantly scented. It is a native of Brazil, so requires hot-house treatment. Award of merit. Shewn by the Director, Royal Gardens, Kew.

Carnation Ivan Lowe.—A very uncommon *Fancy Border Carnation* of medium size and perfect form. The orange buff ground colour is heavily marked with crimson maroon. First-class certificate (National *Carnation Society*). Shewn by Messrs. Lowe and Gibson.

C. Mrs. Edmund Charrington.—This is a superb white-ground *Fancy Border* variety which might well be described as being a paler *Jessie Murray*. The milk white ground is freely marked with thin lines of pale lilac. First-class certificate (N.C.S.). Shewn by Messrs. Lowe and Gibson.

Cladrastis sinensis.—This, the Chinese Yellow Wood, is a rare tree in our gardens. It was discovered in Szechuen and Hupeh in 1890 by Mr. E. A. Pratt. In a native state it is described as being a tree soft, or more in height, but in this country it is, as yet, little more than a large shrub. The branches on view were well flowered, and although individually small, the panicles of whitish, fragrant, pea-shaped flowers were quite attractive. The compound leaves are made up of a variable number of bright green leaflets 3ins. or 4ins. long. Award of merit. Shewn by the Director, Royal Gardens, Kew.

Dierama pulcherrima Heron.—In many respects this might be termed a giant *Sparaxis*; indeed, for a long time the species was included by botanists in *Sparaxis*. It is a native of South Africa and, unfortunately, not generally hardy.

but the erect, toothed spike of pendulous flowers is common and fascinating that it could be worth while risking failure in the hope of being able to grow them. The *Dieramas* from under similar conditions afforded 12s. The new variety was nearly, if not quite, 5ft. high, and had plenty of purplish flowers which

were heavily shaded with maroon on the outside, giving them a fascinating dusky appearance. The common name for the plant is the Wand Flower, a name which is highly suitable. It is a pity that these graceful plants are not more commonly grown. Award of merit. Shown by the Donald Nursery Company.

DWARF CAMPANULAS FOR THE ROCK GARDEN

THE genus *Campanula* is a very popular one, and it contains somewhere about 250 species, including many tall-growing kinds suitable for the border or wild garden and others of low-growing habit only fit for the rock garden planted under special conditions. Many of the latter are charming dwarf rock plants well worth the little care and attention necessary for their welfare. They are also useful and valuable, as they generally flower at a time when early alpine plants are past and flowering plants on the rockwork are anything but plentiful. Their time of flowering extends over most of the late spring and early summer months, and with a number of selected kinds a succession of *Campanulas* may be had in flower for a long period. With the exception of a few of the high alpine species, which demand special treatment, all grow in a good loamy soil mixed with coarse gritty sand. The best situation for most is a half-shady one either on the north-west or west side of the rock garden where they do not get dried up during the warm summer months. There are, however, exceptions which delight in full sunshine and others will grow well under either conditions. As they do not usually root very deeply, it is advisable to mulch occasionally with a mixture of loam and sand and leaf-soil to encourage growth. As a rule they all may be easily raised from seed sown in pots in gritty soil in the early spring; others may be increased by means of division in the autumn or spring; while cuttings may be rooted during the summer months in a close frame.

It is not intended to give a full and extensive list of all the alpine species of *Campanula*, but to limit our attention to some of the best for this purpose. Many of the smaller kinds, charming enough in their way, are more for the collection rather than for providing a display in the rock garden.

C. ALLIIONI (syn. *C. alpestris*).—An early-flowering kind from the Alps of Dauphiny and Piedmont, where it is found between 6,000ft. and 7,000ft. elevation. From rosettes of somewhat glossy green leaves rise on short stalks beautiful purple, trumpet-shaped flowers of large size in proportion to the plant. It is somewhat variable in size and colour and length of stems. Some flowers are very dark purple in colour, borne on stalks 2ins. or 3ins. high, while others have little or no stems. It is a plant for the moraine garden, where the mixture consists mostly of stone chip-pings, and where it must have plenty of moisture during the growing period. It spreads by means of underground growths, which again produce rosettes of leaves away from the old plant.

C. ALPINA, one of the smallest members of the genus, is known as the "Alpine Bellflower." Although it frequently behaves in this country as a biennial, it is a perennial in its native habitat. It is closely allied to *C. barbata*, but, unlike that plant, *C. alpina* prefers soil of a calcareous nature. The plant possesses a fleshy rootstock and forms a tuft of narrow leaves from which the stem, only 3ins. or so in height, is produced. The flowers are bell-shaped and produced in May and June, and vary in colour from pale to deep violet.

It is a native of the Alps of Austria, Lombardy and Transylvania at elevations ranging from 6,000ft. to 7,000ft. Seeds are produced fairly freely, and it is not a difficult plant to grow in well drained gritty soil.

C. ARVATICA (syn. *C. acutangula*).—The stems of this plant are trailing and bear large star-like flowers of purplish blue colour; while the leaves are small, round and toothed. It is essentially a moraine plant, spreading by means of underground stems in the way of *C. Allioni*, and has proved quite hardy under this treatment. *C. arvetica* is found in the high alpine regions of Northern Spain, growing in open stony places. When grown in pans for the alpine house the soil should consist largely of coarse sand and shingle with a little loam.

C. BARBATA is a well known plant with rosettes of hairy leaves and stems up to 1ft. high bearing several large, drooping, pale blue flowers that are bearded within with long hairs. There is also a white-flowered variety. Although preferring a soil free from lime, it is said sometimes to be found growing in calcareous soil. It is found all over the Alps of Europe, but not in the Pyrenees, and flowers in May and June. One of the easiest plants to grow, it seeds freely and grows well in half-shady situations.

C. CÆSPIOSA.—A dwarf creeping plant closely allied to *C. pusilla*, but having nearly sessile basal leaves, ovate or obovate in shape. The leaves of the flower-stalk are stiff, smooth and shiny. The flowers are bell-shaped, somewhat contracted, and produced in May and June. It comes from the Eastern Alps, and likes a loose, calcareous soil in full sun.

C. CENISIA.—A pretty creeping plant with a main central root and numerous stolons proceeding from it, eventually forming a tuft. The stalks are one-flowered and only 1in. or 2ins. high. It is a moraine plant, found on the masses of stony debris of the Alps of Switzerland and adjoining ranges. A somewhat difficult plant to manage in this country, it will grow in limestone or granite, but must have plenty of stones and grit in the soil.

C. ELAÏNIS.—A very attractive species growing in the crevices of the granite rocks of the Cottian Alps, among other places. It forms rosettes of stalked, grey leaves from which are produced branched stems thickly set along their whole length with large, flat flowers of a sapphire blue colour. It is easy to grow in a sunny crevice or on a rocky ledge either in full sun or partly shaded.

C. EXCISA. With underground spreading stems, this rare plant produces wiry stalks 2ins. or 3ins. high, bearing graceful, drooping, bell-shaped, blue lilac flowers. These are remarkable in having a hole at the base of each lobe of the corolla. This species does not flourish in calcareous soils, but requires a mixture of sand, peat and granite chips, but water must be supplied freely. In stony soil it will spread freely, and is a good crevice plant in non-calcareous stone. It is a local plant, only found on the Alps of Saas and the Simplon.

C. GARGANICA.—A very variable but beautiful plant, forming close tufts of light green foliage with numerous stems clothed with small, rounded, rentorn, dentate leaves. These bear light blue flowers of various shades, medium size, bell shaped and almost erect. It requires a place in full sun in rockwork in very gritty well drained loam. It comes from Eastern Italy and Dalmatia, where it grows in the fissures of rocks. There is a distinct form known as *C. garganica* var. *hirsuta* with very hairy leaves, and also a white-flowered variety. *C. garganica* W. H. Paine has larger flowers of a pleasing shade of blue, while the centre

EXCELLENT FOR THE MORAINÉ, *CAMPANULA ALLIONI*.

of the flower is white. It is one of the best free-flowering kinds.

P. HAYLOGGENSIS is a hybrid between *C. pulla* and *C. pusilla*. It is very free growing and flowering, flourishing in half-shady rocky crevices. The flowers are pale blue and bell shaped. *C. Profusion* is a form of this with larger and deeper-coloured flowers. Both are easy to grow.

P. KEWENSIS.—This charming little hybrid *Campanula* originated in the rock garden at Kew in close proximity to its parents *C. exilis* and *C. arvensis*. The plant is intermediate in character, having the habit of the former and bearing the open flowers of the latter parent. The wiry branching stems are about 4 ins. high, bear narrow, sparsely toothed leaves, and produce single flowers on terminal branches. The blooms are rather deeper in colour than those of *C. arvensis*, and are produced in June and July. It spreads freely when planted in stony soil.

C. LANATA.—This striking Bellflower is an ideal plant for a hot, sunny crevice in the wall garden or in some fissure between stones in the rock garden. It is a biennial, but reproduces itself freely from self-sown seed, establishing itself in the chinks and corners where little else will grow. The first year it forms a rosette of grey velvety foliage, the next year it sends up a branching pyramid of large, white to pink, bell-shaped flowers in July. Also known as *C. velutina*, it is a native of the Balkans.

C. LINIFOLIA.—Closely allied to our native *C. rotundifolia* and probably only the mountain form of it. It is distinguished by the narrow, lanceolate, nearly entire radical leaves, and the larger and more numerous flowers. It is a native of the Alps of Europe and flowers in June and July. *C. linifolia* var. *Berkeleyana* is a fine white form of this, while the var. *valdensis* has woolly grey foliage.

C. MACRORRHIZA is found in the crevices of walls and fissures of rocks in Liguria and parts of Spain. It has a thick woody rootstock and sends up numerous twiggy stems with narrow leaves and clusters of pretty blue flowers. A useful plant for the wall garden or sunny ledges, flowering from May to October.

C. MIRABILIS is a handsome biennial from the Caucasus, where only a single plant was found by Alboff in the year 1894. It was growing in a very rocky place, and has a thick fleshy root with a large rosette of spatulate dark green leaves. It flowered in a south border freely at Kew, producing a pyramidal branching stem bearing its pale lilac flowers in July. These are bell-shaped and over an inch long. It should be planted in a rocky crevice in full sun, preferably in calcareous soil. W. I.

(To be continued.)

A Good Yellow Foxglove

If it is not as showy as many garden varieties, *Digitalis grandiflora*, one of the oldest exotics in cultivation, has many meritorious qualities. It usually comes into bloom when the common mauve purple species and its varieties are going off, and from a handsome tuft of deep green, narrow leaves sends up a cluster of flower-spikes to a height of 1 ft. to 3 ft., which bear large, drooping blossoms in a soft ivory yellow. This Foxglove is gifted with a perennial nature, and it will, moreover, reproduce itself from seed. Thus naturalised, *D. grandiflora* can be very effective in the half-shade of the woodland garden or shrubbery. It is an ideal plant for associating with Heathers and native Ferns, and seldom, if ever, becomes a nuisance. It is by no means fastidious as regards soil.

A HEATH GARDEN IN SUMMER

ALTHOUGH the heath garden need never be devoid of blossom from January to December, the season of the true summer-blooming varieties may be said to open with the flowering of *Erica cinerea* in July. This is one of the easiest and best for dry banks or rocky places, in full sun or

The clean rosy pink form of *E. Tetralix*, which is practically identical with the wild form, is a pretty Heath of rather less than medium size, and then there is a variety of a fuller colour, sometimes listed as *E. T. rosea*, which is equally good. Both of these should be included in any collection, and space should be reserved for the

DABOECIA POLIFOLIA, WITH ERICA TETRALIX IN FRONT AND E. MAWEANA BETWEEN.

partial shade, and most of the selected or cultivated forms are much superior to the wild one most commonly seen. This improvement is not so notable in the matter of size as in colour, the garden sorts being of a more definite and pleasing hue, and few of them shew that tendency to bluishness which often creeps into the crimson-purple of the moorland plant.

Erica cinerea rosea is the largest and most effective of its set, and it is also the earliest to bloom with us. This is a magnificent variety for massing, and the big, bushy plants, which keep their shape wonderfully for years, produce a most gorgeous show of colour when covered with their bright rosy crimson bells. The white form of this (in two sizes, minor and major) is not so satisfying, being less prolific in blossoming and the blooms are smaller. But the dwarf-growing *E. c. atropurpurea* is a very brilliant little counterpart of *rosea*, and the still smaller *coccinea*, with bronzy foliage and flowers in an intense crimson-lake, is very choice. This latter appears to be identical with the *atrosanguinea* of some lists.

Erica Tetralix, the Cross-leaved Heath, is another summer bloomer, some of its varieties, notably the white, *præcox*, coming into flower early in July, after which the others soon follow. Though sometimes confused with *E. ciliaris*, there are several clear points of distinction between these two. *E. Tetralix*, for example, is more upright, the growths being stiffer and more bristly than those of the Dorset Heath, which has a soft, more pubescent foliage and more prostrate habit. Then the flowers of *E. Tetralix* are borne in terminal umbels, while those of *ciliaris* are in long racemes and at least a month later.

very pretty white-flowered form with downy foliage known as *E. T. mollis*. There is also a large-flowered silver-pink variety with grey-green foliage which is particularly attractive.

Erica Watsoni is a very distinct Heather and one of singular beauty. It was discovered in Cornwall by Mr. H. C. Watson, and the original plant was supposed to be a natural hybrid between *EE. ciliaris* and *Tetralix*. This combination is certainly suggested by the soft green foliage, somewhat resembling that of a congested *ciliaris*, and the large rose-purple bells which are produced in terminal clusters, these being a sort of compromise between the flat umbels of *Tetralix* and the long sprays of *ciliaris*. *E. Watsoni* is, however, a most desirable Heath, an August-September bloomer, and one that, like all the others mentioned here, is quite content with ordinary light loam.

Yet another variety closely allied to the Cross-leaved Heath is *E. Mackaii*. There is evidently more than one form of this plant, as one may suppose seeing that *E. Mackaii* has been found not only in Galway but in Spain. But the difference, in so far as my knowledge goes, does not appear to extend beyond a variation in habit of growth, some plants being rather more inclined to a straggling, semi-prostrate form, while others are more upright after the style of *Tetralix*. The leaf arrangement, however, follows that of the latter in all cases, but the blossoms, which appear in August and which are a full-toned rose, are shorter and fatter than those of our true Cross-leaved Heath. There is also a double form of *E. Mackaii*, said to have been discovered in Connemara.

E. Maweana brings us back once again to *ciliaris*, of which it appears to be a Portuguese form, though some authorities give it specific rank

and other class it as a hybrid. This undoubtedly true Heath is quite as hardy as clowns, which means that it will do in warm, free soil or sandy peat in all but our bleakest localities. In habit and growth *E. Mawsonia* is free and robust, and the large bells in terminal racemes are a bold crimson.

Of the new *Erica Williamsonii* it is too soon to speak from one's own experience, but plants giving promise of bloom this season are extremely vigorous and evidently mean to do well. This is a hybrid between *EE. vagans* and *Tetralix*, with a leaning towards the former in foliage and, it one may rely upon the memory of a specimen seen at Kew last autumn, with conspicuous heads of flowers in a rich crimson.

In any garden of summer-flowering Heaths the many varieties of *Calluna vulgaris* will give an abundance of colour from mid July onwards. The first of them to flower is the common, or I might write the true White Scotch Heather, of which there are various forms listed by the trade. Another good and larger white is *C. v. Hammondii* and those who wish a still bigger and more branching variety also in white will find their desires fulfilled in a good form (there are some pretty poor ones) of the splendid *alba Serlei*. The variety *gracilis* is also distinct and well worth a place among the choicest.

The crimson-scarlet *C. v. tenuis* is a very distinct early Heath of this group with a strictly medium-sized growth and good habit, and another very desirable form is *C. v. flore pleno*, the double form of our Common Ling. Not all the double-flowered Heaths are by any means an improvement on the single, but this one is really a most charming variety. The habit is tall, branching and vigorous, and when every twig is padded with the perfectly double little flowers in a gentle shade of rosy lilac one feels that the maintenance of a good group of *C. vulgaris* fl. pl. is essential to any plantation of Heathers.

A good many Heaths of the *Calluna* species can hardly be included here, since they do not flower until much later, but *C. v. Alportii* with very deep green foliage and rich crimson flowers, is usually in bloom during August, and the dwarf and mossy *hypnoides* will give colour at the same time. The close-set *Foxii* is also among the earlier ones. This is a useful variety for carpeting any bare spot with its dense foliage, some 3 ins. in height, but it is a shy flowerer here. Indeed, *Foxii* looks as if it had been so persistently nibbled by rabbits or other beasts of the field and troubled by biting winds for so many weary generations that it had yielded up the joy of blossoming for a life of passive resistance towards an unkindly fate.

There is one more group of the *Erica* family which cannot be omitted from among the summer bloomers, and that is *Daboecia polifolia*, which used to be classed under *Menziesia*. The best of the *Daboecias* is the large-flowered white, which is a really choice shrub with foliage of a peculiarly rich green and long, upright spikes of almost globular pure white flowers of great size and substance. These blossoms, indeed, are bigger than those of any other Heather, and they are borne in profusion from June to November. The type species of *Daboecia* has rather smaller, less spherical bells of a rosy purple, but there is a better form of this known as *D. p. atropurpurea* whose blossoms are a more pleasing colour, approaching a full-blooded crimson in a favourable light. *D. p. bicolor* has both white and purple flowers on the same plant, but this is more of a curiosity than anything else. All of these are fast and robust growers in our light, dry loam, making bushes up to nearly 2 ft. high and three or four times as wide, the white form, oddly enough, being much the strongest.

Beautiful as all these Heaths undoubtedly are, and grateful as one may feel towards them for affording so beautiful a display of colour at a season when the garden generally is at its dulllest period, to them alone must not be accorded all the credit for making our Heath slope what it is. For to my mind not the least of the charm that dwells in this part of the garden is due to those wild flowers without which the Heathers would never be quite so pleasing. For "the heath" could hardly "be framed as much as may be to a natural wildness" without some of those native plants one has learned always to associate with the summer moors. Therefore we encourage rather than extirpate all such as blend happily with the predominant occupiers of the place.

The wildings which usually accompany Heaths will, naturally, vary somewhat according to the district, but with us full summer brings numbers of Harebells, than which there is nothing more admirably suited for associating with Heather. There are pale blue tufted cushions of *Jasione montana* (Sheep's Scabious) and colonies of Foxgloves, while coming up in odd places from self-sown seed is *Digitalis ambigua* with its handsome leaves and elegant spikes of ivory yellow flowers. Yellow Cinquefoils and lobelia-blue Milkwort creep among the finer grasses, whose beautiful plumes add their grace to the general effect. To the taller of these grasses, indeed, we owe much at this season, their waving panicles with their soft tones of purple and silvery dun

affording the charm of movement and giving height and character to places which might otherwise appear too uniform and flat. The Air Grasses are particularly lovely, and none of them is aggressive here. As a matter of fact, we have had some difficulty in establishing *A. caespitosa*, one of the tallest and most elegant of British species, this being tender of moister ground than that of our Heather garden. But the silvery *A. caryophylla* grows naturally, and *A. flexuosa*, with its curiously crimped stems, is the Heath's companion over many a wide moor.

Though a pestilence in other places, it is difficult to deny the Sheep Sorrel a place on the more arid slopes, which it will flush with crimson throughout the later summer and far into autumn, and it has a worthy companion in the tall *Hypericum perforatum*, a plant that is included in some trade lists. Another *Hypericum* which is very delightful on the narrow tracks is the little prostrate *H. humifusum*, and the great Tut-an (*H. Androsæmum*) crops up at intervals, its broad-egg-shaped leaves in bold contrast to the finer foliage of the Heaths. All these, together with a few Hawkweeds (*Hieracium*), Oxeye Daisies in moderation, a pretty local form of Golden-rod (*Solidago canbica*) with a short stem and large flowers, and a few more strays give to this part of one's summer garden a flavour of the wild moor which is always refreshing and never detrimental in a dominating sense to the main issue. A.

DWARF AND SLOW GROWING CONIFERS

It is evident to anyone who visits many gardens in this country that there is a growing interest at the present time in dwarf conifers. The daintiness of these plants is in itself a sufficient attraction for many persons. Moreover, they enable people with only small gardens or limited areas available to have represented there types of vegetation which otherwise could not be accommodated. They are particularly suited to rock gardens, for, being almost always evergreen, they provide attractive greenery which not only relieves the winter nakedness and subdues the prominence of stone in such places, but even in spring and summer, when the flower displays are at their highest, adds much to the general effect. The thanks, therefore, of all those interested in alpine gardening, in conifers, and in dwarf trees and shrubs generally are due to Mr. Murray Hornibrook for his admirable little treatise.* The subject is a difficult one, and even a superficial acquaintance with it enables one to appreciate the industry, research and critical acumen which the author has brought to bear in its compilation. He has written a work which few would care to have undertaken and which must for a very long time remain the standard one on the class of plants with which it deals.

There are two types of dwarf conifers, viz., those dwarfed artificially by root restriction, pruning and disbudding—methods of which the Japanese gardeners are the chief exponents; and dwarfs that have originated naturally either as seedlings or, less frequently, as branch sports from normal trees. It is to the latter type alone that Mr. Hornibrook almost wholly confines his attention. They are genuine dwarfs and remain so indefinitely. The others are dwarfed only so long as they are cribbed and confined; released from their bonds and given unrestricted root space they soon tend to regain their normal habit.

It seems as if nearly all trees, if cultivated for long enough a time, will produce certain aberrant forms, such as fastigate, pendulous, dwarf and

variegated. It is remarkable that the common Spruce, one of the tallest, if not quite the tallest, of European trees has produced more dwarf forms than any other. Mr. Hornibrook describes, more or less fully, about fifty of them, the oldest recorded one of which is the well known *Clanbrasiliana*, which the author tells us was discovered on the Moira estate, near Belfast, in the latter half of the eighteenth century. Another well known polymorphic tree is the Lawson Cypress, of which about thirty dwarf or slow-growing sorts are here described. The common Juniper (*Juniperus communis*) has not produced many distinct dwarf forms, but among them is perhaps the daintiest of them all—the var. *compressa*—a tiny, slender, very slow-growing shrub, shaped like the flame of a candle.

What adds so much to the interest of the book is that, besides the descriptive matter, the author gives a full account of the origin and history of each variety so far as it can be ascertained. A reference also to the original description of each variety is given. One can but admire the patient research which has given this work its comprehensive quality. Valuable advice as to cultivation, soil, selection of sites and propagation will be found in it. Very wisely, the cultivator is warned against grafted plants which, worked on strong-growing stocks of their respective types, are forced into more vigorous growth and altered in their habit and characteristics, thereby losing their peculiar interest and value. One encouraging fact the author records is that the only dwarf conifers he has failed to strike from cuttings and thus get on their own roots are the Pines and Cedars. The book is illustrated by twenty-five excellent reproductions of photographs (several of them taken in the Arnold Arboretum), is light to handle, admirably printed and, not least, is provided with an excellent index.—W. J. B.

* "Dwarf and Slow-Growing Conifers," by Murray Hornibrook. Published by Country Life, Limited, 20, Tavistock Street, Covent Garden, London, W.C.2; price 10s. 6d.

CORRESPONDENCE

NOTES ON FREESIAS.

I WOULD like to correct Mr. Jacob in his interesting notes on *Freesias* (page 367) in the paragraph on breaking. I realised the problem of breaking some time ago, but the "rude awakening" when I found one spike of *Wistaria* "broken" made me exclaim, "You brute!" (the rest of the language was not fit for his reverence's ears). By the way, I found a pane of glass close by was cracked shortly afterwards. Was it my language? Anyhow, *Wistaria* is still the apple of my eye, and I have no wish to exchange it for any other variety that I have yet seen. My experience is the same as Mr. Jacob's regarding Mr. Hoog's varieties.—G. H. DALRYMPLE.

AN EXCELLENT PLANT FOR A COOL HOUSE.

MORÆA IRIDIODES is undoubtedly the most handsome of the genus. It makes an excellent pot plant, but it is perhaps more suitable for planting out in a border in the cool greenhouse, where its handsome flowers make it an object of beauty during the early summer. The almost white flowers have broad, obovate, obtuse perianth segments which are clawed at the base, the three outer ones with an orange yellow keel, densely pilose at the base, the three inner segments narrower, with dark markings just above the claw, while the two lobed lanceolate purple stigmas give the flowers a very dainty and effective appearance, as they are borne on the long, slender scape above the dark green rigid leaves, which are from 1ft. to 2ft. long and $\frac{1}{2}$ in. to $\frac{3}{4}$ in. wide, and arranged in crowded fan-shaped basal rosettes. It should be planted in good ordinary soil in a sunny position, and is best left undisturbed all the time it is doing well, giving it plenty of water when growing and in flower, gradually reducing the amount afterwards to

assist in the ripening which is essential to obtain plenty of flower the following season. It can be readily raised from seed, which should be sown as soon as ripe, or may be increased by division, which should be done as soon as the flowers are over. It is said to have been first collected by Thunberg, who gathered his specimen near the Zeekoe River in Humansdorp Division in 1772, but according to the *Botanical Magazine*, Vol. XIX, tab. 693, it was cultivated by Miller in this country in 1758, who received the seeds from the Cape under the title of "White Water Lily," while in Miller's Garden Dictionary, 8th edition, 1768, it is included under the name of *Moræa* vegeta. It belongs to the subgenus *Dietes*, which include all the *Moræas* that have a short creeping rhizome. It might be termed the African representative of the *Iris*, being very closely allied to that genus, and it appears to be very difficult to separate them.

Moræas have no perianth tube, while *Iris* usually have one, also in *Iris* the filaments are usually free, while in *Moræa* they are usually monodelphous.—F. G. PRESTON, *Botanic Garden, Cambridge*.

A DESIRABLE SHRUB.

IT may, perhaps, be of interest to some of your readers to learn that *Desfontainea spinosa* flowers freely in a sheltered though sunny rockery in my garden here, only some fifty miles from London. It is a little bush about 3ft. high and carries fifty blooms besides several buds, and is a most attractive plant.—HENRY G. SKETCHLEY, *Petersfield*.

THOUGH usually listed with the more tender

South American shrubs, *Desfontainea spinosa* is a good deal harder than is generally supposed. It undoubtedly enjoys a warm, loamy soil with free drainage, but in many districts within the sea influence it prospers equally well in a much cooler, stiffer medium. Under favourable conditions *D. spinosa* will grow into a shrub 8ft. in

THE IRIS-LIKE MORÆA IRIDIODES.

height and as much in width, and the foliage, which so closely resembles that of our common Holly, affords a curiously effective setting for the brilliant blossoms. These latter are waxy and tubular, about 3ins. in length and of a dazzling scarlet-vermilion with a clear yellow tip and throat. They are usually borne in the greatest profusion from July to late autumn, and quite small bushes of a foot or so in height will frequently be as floriferous as older specimens. Cuttings struck in a close frame in August should be ready to move the following spring.—A. T. J.

THE BOG PIMPERNEL.

OUR summer moors yield many charming little flowers, but few of them, unless it be the Ivy-leaved Campanula, can rival the Bog Pimpernel (*Anagallis tenella*) in daintiness. This delightful treasure is now blooming freely on many heaths

and commons, its tiny branches with their pairs of round, glossy leaves creeping about almost unseen among the finer grasses and other dwarf herbage which the innumerable blossoms on their upright stems do their best to cover with a sheen of silver pink. Individually, these blooms are larger than those of the common Red Pimpernel, but in colour, form and delicacy of texture they are the last word in refinement and meet companions for the smallest and choicest of our native Campanulas mentioned. *A. tenella* has a reputation for taking kindly to garden treatment where moist ground or bog can be afforded, and it has also been used in a pot whose sides it will drape with its pretty foliage and cheerful flowers. Though in a state of nature it will often be found growing in the dry turf of sandy peat overlying rock to no more than a few inches, it must be borne in mind that even here it always has the saving grace of that close-set mat of fine herbage which is so potent a factor in the conservation of moisture.—CAMBRIA.

DIPLACUS GLUTINOSUS AS A CUT FLOWER.

THE singular merit of *D. glutinosus* as a cut flower is worthy of note, for not only do the branches of this pretty shrub possess to the full that elegance of form combined with a sufficient rigidity which is so valuable a quality in table decoration, but both flower and foliage are eminently beautiful and remarkably durable. How long *D. glutinosus* will remain fresh in water I do not know, but a vase of 18in. sprays before me as I write has been on the table for nearly four weeks, and the last flowers to open, as well as the foliage, are as fresh as when the branches were cut. The blossoms open in succession from the base, and even the smallest terminal buds will develop in their turn into full-sized flowers, the only noticeable difference between them and the earlier ones being a slight failing in depth of colour. Further, as the spent blooms pass off they shrivel up and become almost invisible instead of falling. The shrub referred to here is the orange buff typical form, and this we have found to be as hardy outdoors as a Scotch Fuchsia.—NORTH WALES.

SCENTED-LEAVED GERANIUMS.

A MOST interesting exhibit of scented-leaved Geraniums, which are known mostly as Rose Geraniums, was shewn at the Royal Horticultural Society's meeting on Tuesday, July 24, by the Hon. Vicary Gibbs. The collection, which was admirably arranged by his gardener, Mr. Edwin Beckett, comprised 100 different species and varieties, and was one of the most interesting exhibits of old-fashioned flowering plants that has been seen for a very long time. These Geraniums or, as they are often termed, Cape Pelargoniums are natives, for the most part, of the Cape of Good Hope. Many of the species were imported through the medium of the English Fleet about the year 1795, when it was operating with the Dutch, helping to uphold their supremacy at the Cape. Towards the close of the eighteenth century and early in the nineteenth these plants were most fashionable, and at that time as many as 200 varieties were to be found in this country. Our ancestors were wiser than the present generation in many respects, and in choosing to grow these scented-leaved Geraniums they shewed great foresight, as the plants were easy of cultivation and scented foliage is always a point of value. The Hon. Vicary Gibbs' collection has taken him over thirty years to get together, and I imagine that it would be quite impossible to buy

many of these varieties from nurserymen at the present time.

To an amateur with only a limited amount of spare time and to whom expense is a serious consideration the growing of these *Geraniums* should surely be of more than ordinary interest. The species are very numerous and varied, and although the plants are often impossible to buy, an immense number of species and hybrids are in existence and may be found in all sorts of odd, out of the way corners. Think of the pleasure that may be obtained and the added interest in looking out for these plants in gardens belonging to your friends as well as in the many cottage gardens throughout all parts of the country! Many growers who have just an odd plant or two would be only too pleased to exchange plants or cuttings for other varieties, and in a short time it should be possible to gather together a very choice and interesting collection. During the last year or so these plants have been coming back into favour again and, like the *Streptocarpus*, which came from the same quarter of the globe (South Africa), they do not require great heat, and succeed well in a summer temperature of about 55° to 65°, where plenty of ventilation can be given. In winter, a minimum temperature of 45° down to as low as 40° for the fragrant varieties should be maintained, taking care only just to exclude frost and to allow all the ventilation possible whenever the weather permits. The plants are easily increased by means of cuttings of well ripened wood, which should be struck during August for preference. Some of the varieties are tuberous-rooted and may be propagated from root cuttings, which should be about 1 in. or 1½ ins. long and inserted in sand.

The earliest of these *Pelargoniums* to be introduced into this country would appear to have been *P. triste*, the date of the arrival of this plant being given as 1632. Some of the most interesting include the following: *P. capitatum*, which is largely grown in certain Mediterranean districts by local growers, who distil from the leaves an essential oil which is subsequently used in the manufacture of rose scents; *P. limonium*, lemon *Geranium*, is a garden hybrid with a scent resembling that of balm. There is little doubt that in this case one of its parents was *P. crispum*. *P. crispum* and *P. c. variegatum* have also leaves scented with lemon, while *P. citriodorum* Prince of Orange has small leaves which smell strongly of oranges. *P. rapaceum* Mrs. Kingsley smells of peppermint, and so does *P. tomentosum*, which is rather coarse in foliage with very large leaves. Many scents are included, and among them we have the cinnamon-scented *P. gratum*, the nutmeg-scented variety *P. graveolens*, the filbert-scented *P. Shottesham* Pet, and the delicious almond-scented leaves of *P. Pretty Polly*. A curious species, very seldom met with, is *Geranium gibbosum*, the gouty stalked Crane's-bill. This plant is very distinct in character and has leaves of a shade of sea green, the flowers also being green. The stems are knotty, and will, perhaps, call up unpleasant thoughts among those who are afflicted with either gout or rheumatism, but even they will forgive the plant this failing when they realise that the flowers and leaves possess a delicate fragrance towards the evening. A few other varieties which were shown by the Hon. Vicar of Gibbs included *P. artemisifolium*, *P. ardens*, *P. tetragonum*, *P. Purple Unique*, *P. Westonbirt*, *P. Zermattii*, *P. van Desselii*, *P. Veitchianum* fl. pl. and *P. Moore's Victory*.

If this letter is the means of arousing any interest among other amateurs, the writer will be exceedingly glad, as it seems exceedingly unfortunate that many of the most

interesting and choicest old-fashioned flowers have been so neglected during recent years. —ROBERT W. ASKROFT.

THE HERB LILIES.

THE illustration on this page gives a good idea of the effective use to which these beautiful tuberous-rooted plants (*Alstroemerias*) may be put. In colour the flowers of the different species are almost without rival, with gorgeous tints of orange and pale yellow, red, pink and purple to white. The *Alstroemerias* are among the easiest of plants to grow, and it is surprising that they are not more frequently seen in gardens. Planted at the foot of a sunny wall in a light loamy soil, which may be enriched with well decomposed manure—although this is not essential—they will flourish and increase readily. Here they may be left alone when established, and each June and July they will produce their beautiful flowers in abundance. In cold situations deep planting of the crowns is essential, and it is always advisable to put them from 9 ins. to 1 ft. below the ground-level. Here they are able to withstand

frosts about the same height, but the stems are not so well covered with foliage. The flowers of this species are very beautiful and vary much in colour, and are produced in very large clusters or branching umbels. The four divisions of the flower in some kinds are of a brilliant scarlet red colour marked with purple lines; others are bright rosy pink; in fact, there seems no limit to the various shades produced in seedlings. A charming little plant is *A. pelegria*, which is rather more tender than the other two. It should be protected with litter in the winter, but is well worth the trouble. It grows about 1 ft. to 1½ ins. high and bears clusters of flowers that are white or pale lilac, streaked and suffused with deep rose. The two inner segments are yellow at the base and thickly covered with purple or dark rosy spots. There is also a variety with white flowers.—W. L.

VERONICA RUPESTRIS.

ON page 374 "North Wales" note on "Two Pretty Edge Plants" includes the golden-leaved form of *Veronica rupestris*. I quite agree

A BORDER OF ALSTROEMERIAS.

The Herb Lilies are among the brightest of summer flowers.

frost to a great extent, but in severe winters it is necessary to give a covering of litter for protection. All *Alstroemerias* are readily propagated from seed or division. Self-sown seedlings appear abundantly round about old-established plants, and may be taken up and transplanted to other quarters when necessary. Lifting should be done carefully as soon as the stems have withered. The roots are very brittle and liable to injury and should not be allowed to get dry before replanting. Seed may be sown in the usual way in pots as soon as it is ripe, when it will come up readily, or it may be left till the following spring. Seedlings will flower in the second season after germinating. There are many species, mostly natives of Chili, but the best for general use should include *A. aurantiaca*, which has stems up to 3 ft. high, well clothed with green leaves, and bears clusters of orange yellow flowers in which the two upper flower segments are streaked with red. It is the least variable species. *A. hamantha*

with what he says regarding its merits, but the varietal name is not "Treherne," it should be "Trehane." It came here many years ago from the very interesting gardens of the late Captain Pinwill at Probus in Cornwall, and was named Trehane after his place.—T. SMITH, *Newry*.

ROSE OF SHARON OR ROSE OF JERICHO?

IS it possible your correspondent, "J. B.," Reading, has been confused in the names mentioned above? Rose of Jericho (*Anastatica hieracuntica*) will certainly revive on being placed in water after being kept in a dry state for a considerable time, and it is this peculiarity, no doubt, which your correspondent had in mind and which prompted the enquiry. One can scarcely conceive a member of the *Hypericum* family surviving similar treatment!—H. E. MILLER, *Dewsbury*.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Onions.—Where bulbs are required for next summer, the question of sowing seeds should be entertained. Draw shallow and rather wide drills 15 ins. apart and sow the seeds thinly, selecting one of the winter varieties, such as Tripoli or Giant Rocca. The plants should remain in the seed-bed until next spring, when they should be transplanted. Winter Onions are showing signs of maturity, and they will require watching should wet weather set in, or they will probably restart into growth. The main crop or spring-sown Onions will continue to grow for some weeks.

Cabbages.—Another sowing of seed should be made, and as a rule it is from this batch that the best beds of Cabbages are obtained. Thin sowing will produce short-jointed sturdy plants, which will be less likely to run to seed in the spring.

Lettuce.—A further sowings of All the Year Round, Continuity and Hardy White should be carried out, and earlier sowings may be thinned, the young plants being set out in lines 1 ft. apart to keep up a supply.

The Flower Garden.

Annuals and Biennials.—During the next few weeks a number of hardy annuals should be sown in the open ground to produce a display of bloom after the spring bedding is over. They may be sown in lines or broadcasted where they are intended to flower, but later on it will be necessary to thin the seedlings so that the remaining plants become strong before the winter sets in. A plant that is becoming very popular is the *Eschscholtzia*, of which there are some quite distinct colours. These if sown as suggested will give an earlier and much finer display than those sown in the spring, likewise the Shirley Poppy, also *Coreopsis*, *Larkspur* and the charming blue *Phacelia campanularia*.

Pinks.—The old-fashioned sweet-scented kinds are always appreciated, and now is a good time to lift and divide them. Each piece should have a few roots attached, and they may be planted in their permanent quarters or in the reserve garden for cutting.

Hedges.—Both Yew and Thorn hedges should be trimmed immediately. Specimen trees, especially Yews and other conifers, should have any undesirable growths removed.

Roses.—Those of the rambler type that have finished flowering may have some of the old wood cut out, and the strong basal shoots of the current season should be made secure to the poles. The shoots should be so arranged that they get plenty of light.

Violets.—Remove all runners as they appear, hoe frequently between the plants, and afford a light dusting of soot. If the weather is dry syringe the foliage each evening to keep down red spider.

The Hardy Fruit Garden.

Summer Pruning.—There is quite a difference of opinion concerning the date at which this operation should be carried out, but much will depend on the season. If it is done too early a lot of new growth is produced, the object being to encourage the basal buds to develop without starting into new growth. Apples and Pears are the chief trees to receive attention, and where they have filled their allotted space the shoots should be cut back to within five leaves of their base. Young specimens should be allowed to develop their main growths, and the pruning should be in accordance with the future welfare of the tree. Pergolas, arches, trees on walls and pyramids need pruning at this season, but standard or orchard trees will not require any attention till the winter. Cherries, Plums and Apricots will not need much pruning, such work being done at intervals during their period of growth. We usually do the summer pruning the second week in August, and so far as one can see it will be about the same time this year. All the prunings should be collected and burnt. If woolly aphid is present, apply methylated spirit or petrol with a small sash tool.

Fruits Under Glass.

Melons.—Plants growing in cold frames are producing a useful crop, and at this time every encouragement should be given to help the fruits to finish. Where the fruits are still swelling a little weak liquid manure will be beneficial or, failing this, a light sprinkling of a reliable fertiliser

may be given and then watered in. All lateral growths should be pinched at an early stage, and some of them may be removed if overcrowding is likely to occur. Syringe the plants about three or four o'clock and close the lights for the night. When the fruits approach maturity set them upon inverted flower-pots, discontinue the spraying and admit more air.

Figs.—If any of the pot trees need repotting, now is a suitable time to carry it out. The chief ingredient in the compost should be good quality fibrous loam to which should be added a sprinkling of old mortar rubble and bone-meal. Make the soil firm and do not overwater.

F. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chesham, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Spinach.—Sowing Spinach during the early summer is a hopeless task, as it bolts almost as soon as it appears above ground. However, if sown during the first half of August it will stand, and will prove very serviceable throughout the autumn. A sowing should therefore be made forthwith and another a week hence to furnish autumn supplies.

Saladings.—Transplant or thin recent sowings of Lettuce and make a final sowing for autumn use. It is inadvisable to sow *Cos* varieties at this late date, but one of the larger Cabbage varieties, such as Neapolitan or Tennis Ball, should be sown, also one of the smaller varieties, such as Tom Thumb or Early Ohio. Continue to make small sowings of Radishes and Mustard and Cress, the former every ten days and the latter every week, choosing a cool position in partial shade for this purpose.

The Hardy Fruit Garden.

Summer Pruning.—Those who practise summer pinching will find little cause for summer pruning, but where the former system has not been adopted the latter should now be carried out on Apples, Pears, Sweet Cherries and Apricots, the two former generally claiming most attention. If the operation is carried through much earlier, the basal buds retained are apt to start into growth. Leave spurs about 2 ins. in length, these being again shortened at the winter pruning. It is better to break over the shoots with the aid of the pruning knife than to make a clean cut, as bleeding sometimes ensues when the latter method is adopted. The chief object of this summer pruning is to admit full light to ripen the wood and to enable the leaves to perform their proper functions, upon both of which conditions the fruitfulness of the trees next season largely depends.

Raspberries.—The high winds which prevailed during June played considerable havoc among Raspberries, especially those trained to wires. See that the quarter is cleared of weeds before netting the crop.

Loganberries and their near relatives should have all loose shoots tied in prior to netting them. The wisdom of training this class of plants on trellises will become more apparent when the work of netting the crop has to be taken in hand.

The Flower Garden.

Herbaceous Plants.—See that the tall late-flowering plants, such as *Asters* and *Helianthus*, are sufficiently supported to withstand the September gales, cut away all decayed flowers, and keep the Dutch hoe going among the plants. Do not allow the plants to suffer from lack of water, giving special attention to *Phloxes*, which are very shallow rooters and gross feeders.

Gladioli.—Take care to support these plants as they develop their flower-spikes. Where the plants are in straight lines drive in a few stout stakes and run a line of binder twine along the stretch, to which tie the stems in due course.

Hollyhocks.—Give a final tying to the plants and readjust the ties as necessary. These plants so stretch out that they always drag the ties upwards, making it necessary for the cultivator to slip them up the stake until level or damage will ensue. Both Dahlias and Hollyhocks, being gross feeders, are grateful for occasional weak doses of liquid manure.

Climbers.—Nail or tie in any young growths that are likely to get damaged by winds. Clematises of the Jackmanni type require extra close attention

in this respect. Remove spent blooms as plants go out of flower.

Violas.—Unless the spent blooms are removed at frequent intervals the flowering period is likely to be much curtailed; this is especially the case on light soils. As *Violas* have a preference for cool, moist conditions, attention should be given to watering in droughty seasons.

Lawns should be regularly mown and rolled, and unless the weather proves wet it is best to dispense with the grass box; this, of course, does not apply to tennis courts or where clock golf is played, but the drain that is made upon the grass on those areas will, of course, be made up by top-dressing in due season. Clip all edgings regularly and from time to time "knife" round trees, buildings, vases, etc., surrounded by grass.

CHARLES COMFORT
(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian.)

GREENHOUSE AND CONSERVATORY.

Hydrangeas.—Good strong cuttings should be secured during this month. These plants root readily from nodal or internodal cuttings in a close propagating case with slight bottom-heat at command. The cuttings are best inserted singly in small pots, and when well rooted and growing should be shifted into 48-sized pots. At this stage they may still be grown in the cool greenhouse or in cold frames. In any case they should be placed in cold frames for the autumn and winter, keeping the lights off on every possible occasion. Early in the New Year a batch should be introduced to a warm greenhouse, where they should soon start into growth. By propagating at different periods and by growing them in successional batches *Hydrangeas* may be had in flower for quite a long time. Where it is desired to grow large specimens young plants that have finished flowering should be potted on into suitable-sized pots or tubs, and these may be stood outdoors at the bottom of a sheltered wall.

Mesembryanthemums are interesting plants, but many of them are only of interest to the specialist. There are, however, quite a number of tree-growing species that are well worth growing for any cool greenhouse. The most showy are *MM. falciforme*, *coccineum*, *violaceum*, *Brownii*, *auranticum*, *blandum*, *spectabile* and *roseum*. All those mentioned grow and flower very freely. If cuttings are put in at this time, they will make good plants for next year. As they are all of a fleshy, succulent nature, they do not require to be put in a case, but root quite readily if stood on the stage in a cool greenhouse, in which they may be grown all the year round. They may, however, be stood outdoors in a sunny position after they have finished flowering towards the end of July.

Polygala myrtifolia grandiflora is a South African shrubby plant which is to be common in gardens, but is not often seen at the present day. It is easily grown and makes a fine large specimen, although it has the merit of flowering quite freely in its smaller stages. It is easily propagated at this or any time during the summer by means of half-ripened twiggy shoots. They should be firmly potted and will grow well in any good medium loam with the addition of a little fibrous peat and sand. This plant suffers very much from attacks by white fly, which should be kept in check by the use of an approved insecticide.

Punica Granatum var. nana.—In the South at least the ordinary Pomegranate is hardy on warm walls, as also is the variety *nana*. However, this is very seldom seen, which is surprising when one considers how and with what wonderful profusion it produces its brilliant flowers each year. This variety makes an excellent pot plant, and stock may be raised at this time by means of cuttings of half-ripened wood. Place the cutting pots under a bell-glass in a cool house. If the wood is allowed to become too hard, cuttings from outdoors are by no means easy to root successfully. The best results are obtained by having a stock plant indoors. This plant is naturally of a neat bushy habit, and requires little or no stopping. When the plants attain flowering size they should be stood outdoors in a sunny position during the summer.

Lagerstromia indica, sometimes known as the Crepe Plant, is a very handsome flowering shrub, which is seen at its best when it is planted out in a bed or border. It is usually grown in a warm house, although this is not necessary, as it succeeds outdoors in Cornwall when planted against a warm wall. Thus there is no reason why it should not succeed in an ordinary conservatory. During winter this plant should be kept fairly dry at the root. Early in this year

the previous season's wood should be pruned hard back, as flowers are produced at the end of the current year's wood. Cuttings root readily in a propagating case with slight bottom-heat at command.

Eucomis bicolor and *E. punctata* are both hardy in the South in warm, dry borders in front of plant houses. They are, however, excellent plants for the conservatory and greenhouse, as they flower during August and September, when it is by no means easy to get a variety of interesting plants under glass. As they are rather strong-growing bulbs, they require rather large pots. Good specimens may be obtained by growing four or five in a rein. pot. During winter they should be dried off and stored in a cool, dry shed away from frost. In the spring as they start into growth they may be removed to a cool greenhouse, or even stood outdoors at the bottom of a sheltered wall, where they may remain until they come into flower.

Royal Botanic Gardens, Kew. J. COURTS.

ENDIVE AND LETTUCE FOR WINTER AND SPRING

IN nearly every garden there are borders and plots wherein nice batches of these useful salad plants may be grown successfully during the winter months. In the few gardens where these plants prove troublesome in the open border there should not be much difficulty in rearing them in temporary or permanent frames. A judicious selection of varieties will help matters, too.

Two sowings of seeds are advisable. In northern counties about this time and again in the third week in August. In southern the second week in August and the first week in September. The resultant plants will become well established before really adverse weather comes.

The first sowing in the South may be made in shallow drills where the resultant plants are to remain till gathered for use. The second sowing in the South and both the first and the second in the North should be made in boxes or cold frames, and the young plants resulting transplanted once prior to their permanent planting. The Endive should be planted 1ft. apart in drills 14ins. asunder. The Lettuce 10ins. apart in rows 1ft. asunder. These distances permit of the hoe being freely used between the rows and also ensure a free passage of air between them—two essentials to success.

Cultivators favour certain varieties, and succeed well with them in the majority of cases. For the benefit of the inexperienced I will name those I like best—Broad-leaved Batavian Endive, and All the Year Round and Stansted Park Cabbage Lettuce.

Through every stage of growth there should not be any overcrowding, or failure will result. The best way to avoid this is to transplant when the seedlings are tiny and get the permanent planting done directly the plants are fit for it. Where natural adverse conditions obtain, some protection is advisable in the depth of winter, and if ordinary frames are not available some deep boards fixed on edge and covered with old pea-sticks will form a very good shelter. Rough trifany may be used by itself or be placed on the pea-sticks. At the end of several days or a week's frost all covering material should be left on the plants for at least a day and a night after the thaw comes. This course will prove specially beneficial if bright sunshine follows the thaw. But whenever it is possible fully to expose the plants, do so; and avoid placing empty inverted flower-pots on the plants to blanch the leaves, as in the winter-time they would soon rot.

G. G.

FUCHSIAS IN THE FLOWER GARDEN

STANDARD, half-standard and bush-shaped Fuchsias look charming in the flower garden. They are so useful, too, as the plants are suitable for tubs, vases, and, as standards, for the back of long borders and in beds. Old specimens, not required in the greenhouse, may be utilised to good purpose in the flower garden. When well treated they are quite a success in the warmest corner and are, certainly, very well adapted to cool and even partly shaded positions.

Old plants, growing in pots in the greenhouse, may require a little pruning or cutting back of the branches, but nothing should be done to destroy their naturally graceful habit. A gradual hardening will fit the plants for full exposure by the middle of June, and this can be ensured by placing the plants on the north-west side of a wall or fence when the wind blows from the east and on the south-east side when there is a strong south-west wind blowing. In exposed positions it may be advisable to fix a few stakes in the ground and taster wires to them for the due support of the Fuchsias, and, in the case of half-standards and standards, new stakes must be put to the plants themselves before they are finally planted out. In all cases it is advisable to retain specimens in their pots, plunging the latter to their rims in the soil, or in the grass, as the case may be. Well balanced plants look remarkably fine, growing to all appearance in the grass, their pots being neatly plunged.

Both standards and half-standards may be associated judiciously in a large bed, the soil being covered with such plants as *Violas*, *Pansies*, *Heliotrope*, *Begonias* (fibrous and tuberous). In smaller beds half-standards only should be placed and a single specimen, standard or half-standard, in the centre of a small bed.

A border of plants, varying from 1ft. to 2ft. in height, mixed, look charming, wholly filling it, if overcrowding be avoided. Cultivators who wish to purchase plants will find the following sorts quite suitable, namely, *Avalanche*, carmine and violet, double; *Beauty of Cleveland*, double white; *Champion*, red and purple; *Earl of Beaconsfield*, orange; *Lena*, white and mauve, semi-double; *Mariuka*, magenta; *Molesworth*, double white; *Mrs. Ida Noack*, President, red and violet; *President Felix Faure*, violet, double; *Improved Rose of Castile*, and *Swanley Yellow*, fine habit.

HANTS.

BOOKS

*Delphiniums and How to Excel with Them.**

"A Practical Booklet on the Propagation, Cultivation and Exhibition of these Popular and Beautiful Flowers." The above words appear on the front cover of this very handy and useful booklet, and they are a true index to the contents. Mr. A. J. Macselt, the author, is evidently fond of the flower he writes about in so charming a manner. It is a timely work on a flower that is increasingly finding favour with the public every year, and should command a ready sale. When a particular kind of plant is "taken up" by amateur cultivators generally, the latter never miss a chance of profiting by the experience of expert growers. The author first deals with the evolution and development of the modern *Delphinium*, the varying types and groups, and then helps his readers to some purpose by giving

* "*Delphiniums and How to Excel with Them*," by A. J. Macselt. Published at the Offices of *Country Life*, Limited, 20, Tavistock Street, Covent Garden, W.C.2; 9d. net, by post 11d.

them information about the plant in the garden and for exhibition. These two chapters, together with the one on propagation, will probably be read and re-read with interest and profit by all who become possessed of the booklet. There are also chapters on the "Ills and Enemies of *Delphiniums*" and a brief one at the end of the book on the *Delphinium* as a pot plant, as a cut flower, and some notes on "annual *Delphiniums*." Writers usually deal with the propagation of a plant in one of the first chapters of a book. In this one, however, propagation is the subject of the fifth chapter. It is only a matter of position, as the instructions under this head are to the point and will prove most helpful to the cultivator. The booklet is well written and the information conveyed in a concise manner.—GEORGE GARNER.

Answers to Correspondents FLOWER GARDEN.

LILIES UNSATISFACTORY (F. W. H., Lydney-on-Severn).—Probably the Lilies have not rooted well and the foliage is suffering accordingly. *Brugmansia* may well be planted in May (assuming it is to be grown outdoors) in our correspondent's district.

TREES AND SHRUBS.

VARIOUS QUESTIONS (X. Y. Z., Prittlewell).—*Camphorosma* is a genus of *Chenopodiaceae*, consisting of small shrubs or herbs, chiefly natives of the saline steppes of Central Asia, though the one that our correspondent has (*C. monspeliaca*) is a native of the shores of the Mediterranean. It is not a very hardy plant, and should be grown at the foot of a hot south wall in very well drained sandy soil where protection can be given in winter when required. Seeds of trees and shrubs are obtainable from Messrs. Vilmorin, Andrieux and Co., 4, Quai de la Mégisserie, Paris. *Pseudolarix Fortunei* is a native of China, and should be quite hardy in our correspondent's district. It thrives under similar conditions to that suitable for *Larches*, and may be expected to do quite well in his soil. It is very well known that certain shrubs are hardier near the coast than further inland. All those named by our correspondent (*Styrax*, *Eucallonia lanceolata*, *Akokia quinata*, *Viburnum Carlesii* and *Eucryphia pinnatifolia*) are hardy in the London district and are thriving in the open at Kew. When the cultivation of shrubs on the borderline of hardiness is proposed, positions sheltered from the north and east are usually selected, shelter belts of quick-growing trees and shrubs being planted if required. On large estates suitable clearings are often made in the woodland, while walls and fences facing south and west are made full use of.

FRUIT GARDEN.

INSECTS ON CURRANTS (H. P., Leicester).—The creatures on the Currants are not attacking them, but having fed upon green flies are now in their chrysalis state and will soon become ladybirds. On no account kill them.

MISCELLANEOUS.

CATERPILLARS FOR IDENTIFICATION ("Pash")—The caterpillars are those of the Poplar Hawk moth. If they are in such abundance as to prove detrimental to the Poplar tree (which is unusual), the tree may be sprayed with lead arsenate.

NAMES OF PLANTS.—R. B. B. of E.—*Salvia officinalis* variegata.—G. W. W., W. Wimbledon.—*Campanula carpatica*, native of Eastern Europe.

NICOTINE! NICOTINE! NICOTINE!

No Compound, poisonous or non-poisonous, is as effective or as safe as English-made Nicotine for destroying all sucking insects infesting vegetation. It cannot be bought in a more convenient form for spraying or syringing than as—

CAMPBELL'S NICO SOAP (Nicotine Soap). The best Potash Soft Soap plus 7½ per cent. Nicotine. A teaspoonful will make one gallon of strong spray fluid. Prices:—½ lb., 2/-; 1 lb., 4/-; 10 lb., 32/-.

CAMPBELL'S ENGLISH NICOTINE, 95-98 per cent. This is offered to large users or others preferring to make up their own fumigating and spraying compounds. Prices on application.

CAMPBELL'S NICOTINE VAPORISING COMPOUND. Nicotine content, 50 per cent. Prices:—10z., 1/6; 4oz., 3/9; 8oz., 7/6; ½ pint, 9/-; 1 pint, 17/6; ½ gallon, 61/-.

CAMPBELL'S NICOTINE FUMIGATING ROLLS, very simple and effective. In four sizes for 500, 1,000, 2,000 and 3,000 cubic feet. Prices:—7d., 10d., 1/6 and 2/- each.

CAMPBELL'S PATENT SULPHUR VAPORISER. The best method of exterminating Mildew from plants in greenhouses. In two sizes, for 5,000 and 10,000 cubic feet. Prices:—18/- and 20/- each.

Obtainable from Seedsmen, or, in case of difficulty, direct from the Manufacturer—

J. D. CAMPBELL, Nicotine Manufacturer,

[AUGUST 11, 1923.]

THE GENUS ESCALLONIA

DURING the last few years the Escallonias have increased considerably in popularity. This may be traced to two reasons, the first being that the bushes have done very much better in the open during the mild weather of recent winters, and what is more important for permanent culture, the hardiest species, *E. Philippiana*, has been freely used as a seed parent, giving us a number of hardy hybrids, the best known of which include *langleyensis*, *exoniensis*, Donard Seedling and *edinensis*. We may have to visit the gardens of the south and west to see the beautiful species *EE. macrantha*, *rubra*, *floribunda*, *montevidensis*, *punctata* and others thriving in the open. There are, however, many positions, in all but the most exposed gardens, where Escallonias can be usefully and successfully planted.

Coming from a land of sunshine, as South America is, one important consideration is to select sunny positions for planting. This ensures the better ripening of the wood to stand the frosts of winter. From short-jointed, well ripened wood we also look for more and better flowers. It is also neither necessary nor desirable for the soil to be liberally manured. This would give luxuriant growth, but it is of little use unless well ripened.

In favoured gardens of the South and West, including seaside districts, Escallonias are among the most attractive and beautiful evergreen shrubs for hedges. For localities where the more tender species require protection, the shelter of a south or west wall or fence occurs as the first choice. For such positions they are very suitable. Though when planted in the open Escallonias are free-growing bushes, they may be freely pruned and readily trained as wall climbers. Another position where they may be happily associated with other plants is the shrubby border which is sheltered from the north and east. Here again some pruning each year will be necessary, for the Escallonias make more growth annually than many shrubs, even in poor soils.

So far little has been said about the hardier species and hybrids for lawn beds and massing in pleasure grounds in open positions. With the solitary

exception of the deciduous *E. Philippiana* all are of a free-branching evergreen habit, forming attractive single specimens or groups of plants. Another important consideration is the long period of flowering of several species and hybrids. In mild winters it is usual to see flowers on *EE. macrantha*, *exoniensis* and others in mid-winter.

Escallonias are readily increased by cuttings made of the half-ripened wood of the young shoots in August and September. These root in sandy soil in a frame or under a handlight. If circumstances permit it is quite worth while

cultivating the young plants in pots for two years, when they should be large enough to plant in their permanent positions. The first winter, accommodate the newly potted young plants in a cold frame or unheated greenhouse, following which the pots may be plunged in the ground in a sheltered position until the plants are required for planting in the flowering positions.

Seeds also provide a ready means of increase, but as Escallonias cross freely the seedlings sometimes vary considerably, though there is always the possibility of raising something which is an improvement on the parent plant.

Enough has already been said of the character of *E. Philippiana*, a native of Valdivia, to convey some idea of its value as a hardy deciduous shrub for borders and lawn beds. The flowering season is June and July, when the bushes up to 5ft. to 6ft. or more in height are clothed with small, dark green leaves and an abundance of small starry white blossoms. *E. langleyensis* has for its parents *E. Philippiana* and *E. punctata*, and is, perhaps, the most beautiful of all Escallonias for general planting in gardens. As the name suggests it was raised in the Langley Nursery of Messrs. Veitch about 1893. *E. edinensis* is a hybrid of the same parents raised at the Edinburgh Botanic Gardens, and is not quite so spreading in habit as the former. The habit of the bushes is graceful, being light and semi-pendent. The small, dark green leaves are a pleasing contrast to the rich deep rose blossoms which are freely borne from June until autumn. In addition to its value as a bush in the open, where it grows 8ft. or more in height, *E. langleyensis* makes a pleasing plant for clothing porches and arbours. *E. exoniensis* is reputed to be a chance hybrid which occurred in the Exeter Nursery of Messrs. Robert Veitch. The suggested parents are *EE. pterocladon* and *rubra*. In the garden it is one of the tallest growing Escallonias, a height of 10ft. to 20ft., being by no means uncommon. The rose-tinted blossoms are produced often throughout the summer and autumn. A very promising recent hybrid is Donard Seedling, which with *EE. Philippiana* and *langleyensis* as the

ESCALLONIA DONARD SEEDLING.
A very promising new hybrid.

parents should be among the hardiest of the family. The pink and white flowers are borne during the cooler part of the summer and autumn.

A series of hybrids emanating from Edinburgh between *E. pterocladon* and *rubra*, have been named *E. Balfourii*. They vary in colour from pink to rosy red. We have them growing in the open at Kew and as evergreen wall-coverings with pleasing results. The name of *E. Ingrami* suggests that this old hybrid *Escallonia* may have been raised at Belvoir Castle some years ago. Both flowers and foliage are smaller than *E. macrantha*, from which it is presumed to be a seedling, possibly crossed with *E. punctata*.

A selection of the most attractive species should

include *E. pterocladon*, which some growers class among the hardiest of the family. It was first introduced from Patagonia by William Lobb in 1817. The white flowers are produced from June to early September. A year earlier (1846) William Lobb also introduced *E. macrantha* from the Island of Chiloe. This plant is, perhaps, the most valued of all evergreen flowering shrubs in gardens with a mild climate and by the sea coast, where it is seldom out of flower. Few evergreens rival this shrub as an effective wall or fence covering. Another beautiful wall shrub is *E. punctata*, which produces its rich crimson blossoms from summer to autumn.

This species and its near ally, *E. rubra*, are both natives of Chile. *E. rubra* is generally found to be

a better plant for shrub borders, being rather harder. The flowers are a shade or two lighter in colour.

For walls *E. floribunda* and its near ally *E. montevidensis* are useful late-summer and autumn-flowering evergreens. Both have showy white blossoms. Another white-flowered species which does well in the open woodland at Kew is *E. illinita*. Bushes of this species and *E. viscosa*, also with white flowers, are growing in close proximity. It is interesting sometimes to hear the remarks of visitors with a strong sense of smell. The odour from the leaves of these two *Escallonias* is not offensive, though suggestive of a pesty in the vicinity.

A. O.

TRANSPLANT EVERGREENS EARLY!

THE advent of September should be marked unless exceptionally torrid conditions prevail by the transplantation of every kind of evergreen tree or shrub in need of removal or required in a new position. The writer is strongly of opinion that September is a much better month for such removal than May, though, with care, very successful transplantation can admittedly be carried out in late spring. It is only fair, however, to state that many competent authorities still have a preference for spring planting—at any rate for certain classes of evergreens.

There is just this to be said about the planting of evergreen species and varieties on the border-line

of hardiness that by putting them out they will almost certainly have been in pots—in spring, one practically insures their life until another winter, when they will be a little larger and, on that account, it may be a little fitter to withstand an English winter. This can only apply, however, to a limited number of species. The ordinary range of hybrid *Rhododendron* is hardy enough, so are Yew and Box, for example, while if the Hollies are by no means so hardy as many people seem to think, they are certainly hardy enough to transplant most satisfactorily in early autumn.

The rapidity with which transplanted evergreens emit new roots in very early autumn may easily be tested; that these new roots will continue to

elongate for some time goes without saying and, of course, the plants take up root-growth again as soon as the ground begins to warm up in spring. Given a warm spring and a rather "drippy" summer, little difference will be noticeable as regards growth between shrubs planted in early autumn and those got in in late spring. Given adverse weather conditions, however, the difference is most marked, so that if part of a batch of plants be moved in early autumn and the remainder in spring, one would imagine the following summer that they had been obtained from quite different sources. Every effort, then, should now be made to get the ground ready for early autumn planting.

THE SPLENDID RHODODENDRON PINK PEARL.
Specimen Rhododendrons transplant readily in early autumn.

For young plants of Holly, Laurel, Box and Yew, Rhododendron, Kalmia and what not, it is desirable to arrange removal while the ground is warm; for specimen trees which have not been recently transplanted it is essential. It may be said without extravagance that it is safer to transplant such at midsummer than in mid-winter. Even large specimen Azaleas—deciduous be-

noted—have been successfully transplanted in June. So essential is ground warmth that, given large pieces to transplant and every prospect of, at any rate, a short spell of wet weather, it is often wise to take time by the forelock and carry out the removal during the summer months. We have seen Common Spruce 20ft. tall successfully transplanted at the end of June.

THE BULB ORDER

II.—Daffodils

IF, as I fear, I have left out all mention of either the ancient Polyanthus-Narcissus or the modern Poetaz varieties in my list of what I suggested as useful bulbs to buy for growing in pots, I have made a stupid error for which I can only say, *peccavi*, and proceed at once to make good. Why! if only one can get over the very strong aroma of the old bunch-flowered Daffodils, no one who is uncertain about their being competent to manage bulbs in pots or bowls should omit just a few, at any rate, from their order. One cannot treat them, perhaps, in quite such a cavalierly manner as we may treat that curious tuber—*Sauromatum guttatum*—which needs no soil, but only to be placed on the mantelpiece and it will flower; but they are very easy to manage and anyone who can grow anything in a pot can thing grow these.

Maestro and Mont Cenis with white perianths, and Newton and Bathurst (late), with yellow perianths, are all good. For those who do not care for the strong scent of the old Polyanthus varieties, there are the modern Poetaz. These have taller stems and fewer flowers in their bunches. My favourites are Orange Blossom (white, with large orange cup), Admiration (yellow), and Aspasia (white, with yellow eye.) If for the sake of symmetry I mention a second variety with a yellow perianth, it will be Orange Cup which has a nicely frilled orange cup or eye. As I am on the subject of Daffodils for pots, I may as well continue it. My particular slogan I must repeat once more. "Make use of red cups and red edges for growing under glass." The beautiful red of the eye of Firetail and the delightful orange red of the cup of Bernardino are very transitory delights out of doors unless their blooms are shaded; under glass we have a much longer time in which to enjoy them and under these conditions they need no shade unless in those exceptional years when our friend the sun gives us more of his company than is his wont. Before any other I press the claims of Lady Moore. There is a freshness about the wide yellow cup, with its well defined red edge that sets it apart as something quite out of the ordinary. Blackwell, with its orange red cup is excellent. So is Lucifer, with its still redder cup; although you might never think it, if you judged the flower from the outward appearance of its white perianth. "Things are not always what they seem." It is the opportunity for indulging in red eyes. Ruby, Messina, Ormolu and Acme are four great favourites but I would have to bargain hard to get the four for 10s. 6d. There would be only one of each, I know, but who really wants more if it is the individual flower you wish to enjoy? Why not try a small collection of real beauties, just one of each, and grow them in either 4in. or 5in. pots? But what about the man in the street who wants a few pots for decoration at almost something-for-nothing prices? This is how I would fit him out. Golden Spur, Madame de Graaff, Victoria, Lucifer, Fairy Queen and Aspasia.

I now pass to varieties to buy for out of doors. Let me suppose I had no Daffodils of any sort in my garden and that to make a start my choice had

to be limited to three. I would go to old and well tried varieties and select Emperor, Barrii conspicuus and Poeticus recurvus. This does not mean that I would brush aside all the beautiful

DELIGHTFUL FOR POTS, THE ORANGE CUPPED BERNARDINO.

creations of the last quarter of a century did I wish to add some good varieties to those that I already had. I would then think about Lord Roberts as a yellow trumpet and Duke of Bedford as a bicolor trumpet and Philippe de Vilmorin as a white trumpet. This last named won its spurs in the bank on the way to the Rock Garden at Wisley, where my good friend Mr. Wright used to tell me it attracted an immense amount of attention from visitors. Among the larger cups (*Incomparabilis*) it would be Lady Margaret Boscawen and Steadfast; and if the soil were light, Lucifer and White-well. In the Barrii, with their smaller cups, certainly Seagull, possibly Sunrise, Miss Willmott, Incognita and Firebrand. The giant Leedsii are a splendid type to go in for, as now we have them with longer stems. The pick of the bunch is with

many The Lawn, but it is expensive as yet. The series raised by Mr. Duncan Pearson are now fairly low in price and a trial of Norah Pearson, Lowdham Beauty or Mrs. J. L. Franklin might be useful. My mind is soon made up about the small cupped Leedsii, White Lady, Evangeline, and if it can be obtained, Countess of Southesk. Two Triandrus hybrids are cheap enough to buy by the dozen, e.g., Queen of Spain and J. T. Bennett-Pöe. The Poetaz section gives us many good garden plants. Those who have never tried them might well include one or two in their 1923 order. They are quite hardy—at least all those raised by Van der Schoot—and I would suggest Elvira, Jaune à Merveille and Klondyke. He is a bold man who ventures to pick out Poets. So many are on the market. Different firms have their particular specialities. No one should be without the true

old "Sweet Nancy" (*Poeticus recurvus*). If it were the "latest out" of our raisers, everyone would be mad to have it. After this I would order Sonata, Matthew Arnold and Virgil, as they are different in build and do not all bloom at quite the same time. Now for a few odds and ends. How about the diminutive *juncifolius*? I have heard of a practical joke which was played upon the judges at a famous Cornish show, when some dark *Viola gracilis* flowers were bunched up and scented so as to pass for single Violets. If the blooms of *Narcissus juncifolius* were put at the ends of the beheaded stalks of the single Bachelor's Buttons it is possible that they might pass for Buttercups. So far, however, from their stems being tall they seldom exceed 4ins. The places for these little fellows is either a cosy nook in the rock garden or in small pans in an alpine house. As an extreme contrast in their flowers, some cyclamineus might be bought at the same time. It likes semi-shade, so a shady place ought to be found for it. The finest

colony I ever saw was in semi-woodland in the late Mr. Andrew Kingsmill's garden at Harrow-on-the-Weald. It is excellent in small 4in. pots in an alpine house.

Doubles rather leave me cold. I except the pretty creamy Argent on account of the loose mixed-up arrangements of its perianth and corona. I would couple Volcano (a jazz mixture of red and yellow) with it, but half a guinea or thereabouts is a bit stiff for a double variety. Campenelle Jonquils (*odorus rugulosus*) bring my suggestions to an end. Not long since I was asked if the variety was hardy. As far as I know, it is hardy here at White-well, but never having taken any particular notice of it as it used to grow where it liked, I should not like to say that it is in very severe winters. It is a gem for cutting.

JOSEPH JACOB.

RANDOM NOTES FROM AN AUGUST GARDEN

ONE of the pleasantest objects to dwell upon during the hot and droughty days of the last few weeks has been a colony of *Linaria pallida* var. *alba*. This has all the beauty of foliage and size of bloom that distinguishes the lavender type, but its lovely white flowers, with their yellow noses and delicate fragrance, give a cool and refreshing touch to the elegant and sappy leafage. Like the typical plant, this white form is not quite so aggressive as most of its kind, but even if it were more so its merits are sufficiently alluring to claim for it some shady, safe and stony corner over and through which it may range at its own sweet will. *L. requitriloba*, the tiniest of all, should also be found a congenial home and even suffered if need be, and another good and later bloomer of this family is *L. origanifolia*. So far this last has shown no signs of that ungovernable lust for trespass so characteristic of the creeping *Toadflaxes*. On the contrary, it forms a humble, semi-prostrate little mass of slender stems and rounded, rather hairy leaves, and bears in August a profusion of clear lilac flowers which are very nearly blue in evening light.

Very delightful about the drier slopes and ledges of the rock garden just now are those *Harebells*, which, though they all bear unmistakable traces of *Campanula rotundifolia* in their habits, forms and colours, owe much of their variety to the influence of some of the cultivated species. These pretty, nameless straws are not only very lovely in themselves, but they crop up and lend their colour and grace to many spots that would otherwise be rather dismal and never intrude. Some *Campanulas* of this class have, of course, been named, and they deserve it, one or two of the whites being singularly beautiful. A *carpatia* × *rotundifolia* hybrid, whose name I have for the moment forgotten, is a really choice variety, and among other dwarf *Campanulas* to which one owes much these later days are *C. haylodgensis*, *Profusion*, *Norman Grove*, and the alpine species, *arvatica*.

In a warm, dark corner there is a little bushing, *Felicia abyssinica*, with narrow, dark green foliage a few inches above which stands on slender, erect stems an array of composite flowers, yellow-centred and with very fine, hair-like rays in a clear lavender. *Felicia* has not yet proved her staying power during a real wintery test, and it is possible that the time may come when *Dolores* will be engraved on her label instead. However, she is one of the happiest plants to-day, and I

wonder it she is the same individual which one remembers having cosseted years ago under the still prettier and appropriate name of *Felicia tenella*.

Hereabouts, where even the "bone-drys" are beginning to suffer the virtuous discomforts of total abstinence, one regret has to be chronicled. *Sedum corulescens*, which used to arrive every summer with a haze of azure, has failed us this time, and there is nothing more in annuals beyond a few dwarf *Eschscholtzias* (*caespitosa* and *tennifolia*) and some stray roots of *Leptosiphons* to take its accustomed place about the spring plants which are "resting." One perennial *Sedum*, however, among others in this sun-baked desert insists on notice, and that is *S. murale*. This is not an uncommon plant, but its crimson purple foliage and true heads of starry flowers in dazzling

THE PRACTICALLY LEAFLESS "WAIT-A-BIT," *RUBUS AUSTRALIS* PAUPERATUS.

rose madder and white, held erect on 8 in. stems, make a cheerful mass of colour. *S. murale* is said to be a form of *S. album* which is ramping in a carpet of pinky white foam elsewhere a useful old plant that will resist like a lichen the hottest sun and most deadly drought.

Though most of the *Erodiums* have had their day, *E. chamaedryoides* (Reichardt), perhaps the most precious of all its charming race, still carries on with extraordinary persistence, and the new rose coloured form, not to be outdone, is hardly less brightly adorned with its larger, prettily veined blossoms. *Geraniums cinereum* and *argentum*, which have been in bloom all summer, rejoice in the hottest and driest places of the rock garden, and will continue to give us their choice

little bluish white flowers for a long while yet. Much more cautious is their relation, *Pelargonium Endlicherianum*, which hesitates to open its rosy crimson blooms until August is here. Though not difficult in any free, warm soil or limestone crevice, this alpine seems to be still uncommon in gardens, but it is well worthy of a fuller recognition for its own sake and also because it is the only *Pelargonium* known to me which appears to be tolerably hardy. The leafage is much like that of the common or garden *Geranium*, but of course rather smaller (the plant being about 1 ft. high) and fragrant.

Another uncommon little thing on this part of the rock garden is *Rosa Roulettii*, said to be the midget of its noble tribe, and one can hardly conceive any Rose being much smaller. Though *R. Roulettii*, which I am told comes from the Pyrenees, is reputed to attain the stature of 6 ins., the specimen referred to has not yet reached 3 ins., and if the howls of the air will never roost in the branches thereof *R. Roulettii* insists on emphasising the fact that it is not a deception by producing a long succession of little double pink Roses, each about the size of a sixpence.

Very different is the case of *Rubus australis pauperatus*, which might be anything from a bundle of rusty wire to the jiggumbob of some elfin gardener. This plant has given up growing foliage, contenting itself with the stems and ribs of leaves only, and these it has armed with rows of fierce little teeth, the result being a confusion of naked, springy, prickly, rectangular branches which seem to exist for no definite object beyond that of looking spidery and exciting the interest of the curious.

By way of contrast there is a peculiar attraction about the soft and squat rosettes of *Teucrium pyrenaica*, a gentle, mouse-like appeal for recognition, if not pity, and this impression is never so irresistible as it is in these later days when the downy cushions swell in the August sunshine, and out of their scalloped leaves peep the rows of chubby little flowers in cream and lavender. It would be hard to deal other than tenderly with this pathetically humble creature. A more showy affair is the silvery-leaved, golden-flowered *T. aureum*. This is really a choice plant, but it is not blest with a hardiness sufficient always to carry it through a wet winter. More reliable than this latter is *T. ackermerus*, also a white-leaved shrublet whose foliage serves so well as a foil for the terminal whorls of bright rosy-crimson flowers which appear in July and later.

Allied to the *Teucriums* are the *Betonias*, but I do not know that any of these possess commendable virtues outside the herb garden, save the variety *superba* of *B. grandiflora*, which is a showy woodland or mixed border plant for late summer in sun or shade. *Stachys corsica*, another of these multitudinous labiates, is cheerful as a carpet for a very dry place during these droughty days, and *S. coccinea* is a handsome Mexican species which will be a blaze of red throughout the later months. Then there are several *Scutellarias* and *Micromeris* (*Satureia*), which can also be put to good use in warm, sunny spots.

To *Saponaria* and *Silene* we owe not a little at this season, for the former gives us *S. ocyroides* in white and various shades between pink and a full-blooded crimson, all good and hearty doers under most trying conditions. Then there is much to be said for the double *S. officinalis*, one of the very few hedgerow plants that indulge in double flowers and show no signs of reversion to type. This can be a rampant spreader and is not a plant choice enough for the border, but in the open woodland or margin of shrubbery its bold heads of clear, rose-pink flowers can be very effective throughout the "back-end."

N. WALES.

DWARF CAMPANULAS FOR THE ROCK GARDEN

(Continued from page 401.)

C. MORLITANA is somewhat difficult to grow in this country, but under conditions which suit some of the *Androsaces* of the *Aretia* group it will thrive with a little trouble. It should be planted in a crevice with a southern exposure in soil of a calcareous nature. It is a pretty little plant from the Southern Tyrol, where it is found at elevations between 2,000ft. and 4,000ft., in the fissures of rocks. The leaves of the base are orbicular-cordate and stalked, while those of the stems are smaller and ovate. It is hairy all over, with stems bearing single, large, violet-coloured flowers in June and July.

C. MOLLIS is a white, woolly-leaved little perennial from Spain, forming tufts of small obovate

leaves, with trailing stems, terminating with three or four large, pale purple, bell-shaped flowers in July. It is a plant for a hot, sunny ledge or crevice. Like many other *Campanulas* this is a favourite food for slugs, so a zinc collar should be used for its protection.

C. PIREA.—This is one of the rarer species, the true plant is seldom seen in gardens. It is a native of the Maritime Alps and Northern Italy where it grows in calcareous rocks. It has a thick fleshy rootstock, soft woolly leaves and leafy stems bearing heads of pale yellow flowers. More interesting than attractive, it requires to be grown in a sunny crevice, coming into flower in August and lasting for a considerable time.

THE DAINTY LITTLE CAMPANULA PUSILLA.

LIKE MINIATURE GATLING GUNS, CAMPANULA ZOYSII.

C. PORTENSCHLAGIANA (syn. *C. unralis*).—A most useful rock plant from Dalmatia, closely allied to *C. garganica*, but differing in its stoloniferous habit. It is of tufted growth, with small, cordate, dentate leaves, and flourishes either in sun or shade, soon covering a good space. The drooping violet flowers are bell-shaped and produced on trailing branching stems in great protusion during the summer months. There are two distinct varieties in cultivation, the large-flowered one from Bavaria being known as *C. Portenschlagiana* var. *major*. It is one of the most easily grown species and readily increased by division.

C. PULLA.—A beautiful little species of stoloniferous habit, forming quite a tuft of small rounded leaves. The stems are one-flowered, the flowers being bell-shaped, drooping and of a rich violet colour. It is a native of the Alps of Austria, usually found growing in mountain debris, and requires a soil rich in humus, but with plenty of broken stones to give perfect drainage. It flowers in July. There is a variety with lilac-coloured flowers known as *C. pulla* var. *lilacina* of the same habit and quite as free.

C. PULLOIDES is a larger-growing plant, with much larger, deep violet flowers, probably a cross with *carpatica*, as is *C. "G. F. Wilson."* The latter is a tree-growing plant one form of which has dark green leaves and deep violet flowers, while the other has yellowish foliage.

C. PUSILLA.—A pretty and most variable species found throughout the Alps in calcareous regions, growing in the mountain debris. Very near *C. caespitosa* in habit, it is often confused with that species. It is one of the easiest to grow, as well as one of the prettiest of the dwarf *Campanulas*, flowering from June to September, flourishing in sun or shade. The flowers are bell-shaped, borne on stems 2ins. to 4ins. high, and varying in colour from blue to lilac and pure white. A sandy loam, with plenty of broken stones intermixed, is suitable for this plant, in which it will spread quickly and increase by means of stolons and self-sown seeds. *C. pusilla* "Miss Willmott" is a pale blue or lilac form and there are numerous other named varieties of different shades of colour.

C. RAINERI.—From the Eastern Alps this is a charming little plant, with flowers varying in colour from deep blue to pale lilac. It grows only a few inches in height, with sturdy stems, thick tomentose leaves and large, erect flowers in July. It is a plant for moraine conditions with plenty of grit in the soil and thorough drainage, in full sun if there is plenty of moisture, but in half shade if conditions are drier. There is also a form in gardens with less erect flowers and greener foliage, probably a hybrid with *C. carpatica*. Although inferior to the type it is well worth growing.

C. ROTUNDFOLIA.—A well known native plant, that is also distributed throughout Europe and Siberia. It forms tufts of leaves of which only those at the base are rounded, from which arise the branching stems, bearing a profusion of bell-shaped flowers in various shades of colour, from violet-blue to white during the whole of the spring and summer. There are numerous named varieties grown in gardens, of which the most distinct is var. *soldanelliflora*, with double flowers. It reproduces itself from self-sown seed (not the double form) and is very useful for the larger rock garden.

C. SAXIFRAGA.—A handsome rock plant from the Caucasus and Armenia, with a thick fleshy rootstock, a rosette of lanceolate leaves that are pubescent on the margins, and short, one-flowered stems about 3ins. high. The flowers are large open funnel-shaped and rich violet in colour, usually produced in July. It is one of the kinds which dislike lime, but thrives in well drained gritty soil and is readily increased by means of seeds or cuttings.

Slugs are very fond of the leaves and are generally the cause of failure with this plant.

C. SCHNEUCHZERI.—Very near *linifolia*, distinguished chiefly by its one-flowered stems and larger flowers; a higher alpine form.

C. SPECIOSA.—A beautiful plant from the Pyrenees, usually found in limestone debris at the foot of rocky clefts. It has the root system of *C. Allionii*, spreading by means of underground stolons, with tufts of narrow undulated leaves that are covered with hairs. It grows about 1 ft. high, with branching stems, and large, drooping, bell-shaped flowers, varying in colour from violet blue to pure white. It requires moraine-like conditions in full sun, with plenty of moisture. The flowers are produced in July.

C. SPICATA.—A biennial from the Southern Alps and Carpathians, with downy and roughly haired leaves and stems 1 ft. or more high. The purplish flowers are borne on long, erect spikes in summer. It is easily raised from seed and grows well on sunny ledges.

C. STANSFIELDI.—A charming low-growing perennial in the way of *C. Waldsteiniana*, but with larger and darker violet-purple coloured flowers. It is of garden origin, growing about 4 ins. high, with numerous leafy stems, and open, bell-shaped, drooping flowers in July.

C. STEVENI.—From the Caucasus, this is more of a pasture-loving plant, with mats of dark green foliage, the leaves of which are broader at the apex. The blue flowers are produced on stems up to 1 ft. in height. It is easily grown in half-shady positions in rich soil.

C. THYRSOIDES.—A plant of the limestone Alps up to 6,000 ft. elevation, growing in rocky fissures and heaps of debris. Of biennial habit, with narrow, downy leaves in the form of a rosette, from which arise the stout stems up to 1 ft. high. The pale yellow flowers are borne in dense spikes on the upper half of the stems in June and July. It produces plenty of seeds and is easily raised in spring. The seedlings should be planted out in autumn in a well-drained sunny position.

C. TOMENTOSA.—A biennial species from Greece, where it is found growing in rocky crevices and fissures in full sun. The silvery, downy leaves of the first year's growth are produced in rosettes, from which arise in the second year the trailing stems, bearing the pale lavender flowers. It is subject to damp and should be planted in vertical positions where absolute drainage is secured.

C. TOMMASINIANA.—A pretty species from the Dolomites, growing about 9 ins. to 1 ft. in height, with branched, erect, wiry stems, narrow leaves and long, narrow, bell-shaped, lilac-blue flowers in July. It is sometimes given as a synonym or variety of *C. Waldsteiniana*, but it quite distinct from that plant.

C. TRIDENTATA.—Closely allied to *C. Saxifraga*, from which it is distinguished by its wider, oblong, spatulate leaves, that are ciliated and tipped with three or more crenulate teeth. The flowers are blue and borne on stems 3 ins. or 4 ins. long in July. A native of the Caucasus.

C. WALDSTEINIANA (syn. *C. flexuosa*).—A choice little plant from the Alps of Dalmatia and Croatia, where it is found in the fissures of rocks. It is of erect growth, making compact little bushes 3 ins. to 4 ins. high, with narrow leaves on wiry stems, terminating in erect, open, bell-shaped flowers of a blue-violet colour. Grows well on a sunny ledge in sandy loam and is easily propagated by means of division, or raised from seeds sown in spring. *C. Wockii* is evidently a hybrid between this species and *C. Tommasiniana*, being quite intermediate in character.

C. ZOYSII.—A rare and beautiful little plant, only growing 2 ins. high, making neat little "bushes," with ovate green leaves. The flowers are small,

usually in threes, fringed or hairy inside, light blue in colour, with the corolla somewhat contracted. It requires moraine treatment, and flowers in

June and July. A native of the Eastern Alps, generally growing in the debris of calcareous rocks at about 7,000 ft. elevation. W. I.

LILIES IN THE GARDEN

(Continued from page 395.)

THERE are many places in the herbaceous border where groups can be introduced with wonderful effect, and in this position Lilies have the advantage that most of them prefer to grow mingled with other plants that will afford shade to their roots. Pæonies and Lilies make a fine combination, especially if the later-flowering Lilies are chosen. Pæonies flower early, and when they are over their foliage gradually deepens in colour to warm ruddy browns, bronzes and rich greens flooded with varying tints. Any of the orange-coloured Lilies rising from such foliage gain much in effect from the combination and more from the shade that the overhanging Pæony foliage casts upon the Lily roots. One remarkably successful planting comes to my mind of a broad pergola-covered walk over which trailed Vines, Honeysuckles, Roses, Clematises and Passion Flowers flanked by borders of Pæonies. Early in the year the front edges of these borders were bright with Crocuses, *Iris reticulata* and Anemones. Later, the Pæonies formed banks of rich colour and, later still, there rose masses of *Lilium croceum*, *candidum* and *tigrinum splendens*. There were other Lilies also, in smaller groups, but these three varieties formed the main plantings. The value of the Madonna Lily planted against the columns of a pergola has been illustrated so often that it is well known.

It is, however, in the half-shade of thin woodland where leafy deposits have enriched the soil, in

the open spaces between Rhododendrons and Azaleas, Heather plantings and kindred shrubs, and in other similar positions that most of the Lilies love to dwell. In borders on the shady side of a wall, among Ferns, Epimediums and such dwarf foliage plants, many of them thrive admirably, and there is something in the very thought of Lilies and Ferns that strikes a note of delicious harmony.

To the would-be grower of Lilies who has had little experience of them there is a very simple rule that can be followed with advantage. Stem-rooting Lilies require shade at the base. Many species produce two sets of roots, one at the bottom of the bulb, the other at the base of the stem just where it emerges from the bulb. These are known as stem-rooting varieties. Without sticking too closely to scientific accuracy, it can be broadly asserted that these two sets of roots perform different functions. Those at the base of the bulb feed and keep it in good, healthy growing condition, and start into growth long before the stem appears. The roots that appear at the base of the stem are primarily responsible for the development of the stem and flowers. There is evidence of this in the fact that a slug may eat off the stem in its young condition, and the bulb to all appearance will lie dormant for a season and yet all the time it is going on growing underground unperceived, and at the end of the season will turn up as good or a better bulb than those in the same position that have flowered. But, if for any

THE WELL BELOVED MADONNA LILY, *LILIUM CANDIDUM*.

reason, one of this class is unable to produce stem roots, or if they are injured in any way by being dried up through lack of shade, for instance, the stem and flower suffers. Hence both sets of roots are equally important, and if the bottom ones are provided for at the time of planting by suitable selection or preparation of the soil and the upper ones by arranging shade for them during the growing season, success is ensured.

If, however, the stem roots are watched and when they appear above the ground a light mulching of soil, leaf-mould and sand, and in some cases a little old manure, is applied so that they can take hold of it, the result will be a great gain to the strength of the *whole plant*; because, obviously, if the stem roots fail to function, the plant will extract all its nutriment through those at the bottom of the bulb, which will thus have a double burden placed upon them and be unable to maintain both bulb and flower-stem in full vigour. The probabilities are that the bulb will be the sufferer and will become so weakened that the whole plant will succumb to the first attack on its constitution it receives.

More than half the failures to grow Lilies in the garden can be attributed without hesitation to the failure of these stem roots to perform their natural function, and this is, almost without exception, due to neglect to provide for their simple requirements.

Another point upon which the grower of Lilies for the first time will, naturally, seek information is the depth at which they should be planted. This, again, is to some extent a matter of the variety, but as a general rule it will be safe to adopt the principle of planting them about three times the depth of the bulb. Very few of the stem-rooting Lilies should be planted less than 4 ins. or 6 ins. deep, and certainly none of the stronger-growing sorts should be nearer the surface than this, especially if they are autumn planted, as it gives them a better protection against frost. Another advantage in deep planting lies in the fact that the stem roots will be produced, in all probability, below the surface of the ground, and therefore be in a position to undertake their duties as soon as they commence to grow. Some growers advocate leaving the hole in which the bulb is planted partially filled in until the stem has commenced to grow and the upper roots have appeared. The theory is, I believe, that the stem is not likely to be crippled in its young state when emerging from the bulb, and also that it compels the bulb to make its bottom roots first. There may be something in this, although I do not think it is worth much consideration. There can, however, be no objection to such a course providing the necessary attention is given *immediately* it is required.

Having planted your bulbs, remember one cardinal point: No Lily ever likes to be dry at the root. Some, like the Bog Lilies I have mentioned, love to be permanently damp. The others, although they may prefer varying degrees of moisture, will none of them succeed under drought conditions. Stagnant, wet soil they do not like, but even during the winter, their resting season, they would rather be damp than dry. See therefore that during the growing season they have sufficient moisture to maintain healthy, vigorous growth, and do not forget that if you neglect this the growth may appear to be quite healthy above ground, but it is probably being maintained at the expense of the bulb below. *Lilium auratum* has been known to flower well and strongly, and virtually eat its own bulb in doing so.

In the article last week I indicated the broad principles that must be adopted by the would-be Lily grower, but purposely omitted one

important point in writing of the various soil conditions likely to be met with in the English garden. It is, however, one that is bound to arise and, before going on to the various sections of the genus in detail, must be dealt with. The statement has frequently been made that Lilies do not like lime. In the main this is true, but lest it should deter those who accept it, as literally applied to the whole genus, from trying to grow *any* Lilies in a limy soil, it needs a considerable amount of qualification. The fact is that some of the most popular and also the most beautiful species thrive in soil containing a considerable proportion of lime, and a very large number of the remainder can be quite successfully cultivated by a little careful attention being paid to the actual areas in which they are to be grown.

The expenditure of time and cash involved in such preparations is, compared with that necessary for doing the same thing for some of the lime-hating shrubs, very small indeed. If you plant shrubs, such as the *Rhododendrons*, that object to lime, you know that to whatever extent you prepare the position for them, if they succeed as they should, they will eventually outgrow it, and that the time will come when, unless further drastic operations are undertaken, the shrubs will suffer. The root action of Lilies is, however, much more local and the areas it is required to plant always very much smaller than in the case of shrubs. A square yard will accommodate a very fine group of Lilies, and the original preparation will avail longer than it would be wise to leave the bulbs undisturbed. But this special preparation is only necessary in the case of some of them. In the case of others lime may even be introduced into and around the space for the purpose of protection against slugs, and is recommended in some instances for the purpose of preventing the soil turning sour. It must, however, not be forgotten that there are some species that must be protected from contact with lime in any form. To avoid repetition I shall indicate later those that do not object to lime.

Before leaving this question of cultivation there is just one more remark regarding the preparation of soil that I should like to make. No harm will ever be done, and often much good will accrue from the introduction of charcoal, or wood ashes, or both, into the soil.

Now there is another question that will invariably occur to the garden lover who is contemplating the introduction of Lilies into the garden. Are they hardy? The answer must depend entirely on what the enquirer understands by the word hardy. They are more hardy than a Potato. They are much more hardy than most of the

Gladoli. With a few exceptions they will succeed under the same conditions that you would give to a Darwin Tulip or a Hyacinth. Protected with a moderate covering of earth most Potatoes will

STRONG SPIKES OF THE YELLOW AND CLARET LILIAM
MONADELPHUM SZOVITZIANUM.

survive an ordinary English winter and make new growth with the advent of spring, but a considerable number of them would rot if the earth around them were frozen. Well, with few exceptions, that is of those varieties that come from warm climates, Lilies are hardier than that. Actual frost does not affect them severely if they are planted properly, and have a sufficient covering of earth over them, and the required covering is no more than will be beneficial to them in other ways. Stagnant moisture around the bulbs, particularly in winter-time, will injure them. So important is this that it is worth reiterating that the very first essential for successful culture is thorough drainage. There are a few sorts that should never be planted out of doors.

It is risky to enumerate those that, on account of their delicacy of constitution or for other reasons, are unsuitable for outdoor culture, because conditions vary so much in Britain that what are considered hardy in one county are hopeless in another a hundred miles distant. *Lilium sulphureum* is an example. This, one of the finest of all the trumpet Lilies, flowers so late that in none but the most favoured districts can it develop its flowers to their full beauty before the early autumn chill ruins the buds. And yet I have known it, with moderate shelter, in an exposed, bleak position near the East Coast develop some marvellous flowers when the autumn was favourable. I have also seen it spotted with brown, bruised,

and jockeying in the cold autumn rains, with a feeling of sadness that so much beauty should be wasted because of the absurd fascination the growing of tender plants out of doors has for some people. Success one year in five may be enough to repay some people for failure during the other four, but it is sinning against bountiful nature to withhold just the slight protection of a cold greenhouse, which is all that is required to ensure success.

When we consider the widely distributed districts from which the Lilies now in cultivation have been collected, it is surprising that so many of them can be grown with comparative ease in English gardens. From the Pacific slopes of California westwards to Japan, throughout the southern half of the temperate zone, the majority have been found, some few hailing from hill districts south of this line, and one or two have existed north of it, beyond the reach of records. Most varieties have come from districts that experience greater extremes of heat and cold than is common here. Hence the conditions obtaining with us are generally suitable for successful culture, saving only the excessive wet, combined with low temperature we sometimes experience. On the whole, most of them enjoy a moist climate, but they do not like cold moisture; they will however stand this better than intense, dry heat. It is not often in our "island story" we have had to bemoan this latter condition.

Now, with regard to the varieties that should form a nucleus of a collection that can be extended as experience and the desire grow. Of course, no English garden is complete without the oldest of all known species, *Lilium candidum*, or as it is popularly known, the Madonna Lily. Its stately purity has shed its fragrance in the gardens of peasant, poet and peer ever since the garden in England became that quiet retired place, shut off from the intrusion of the busy world without, and closed to the inquisitive gaze of the restless multitude that makes "the world." Just a green hedge, the fragrance of Madonna Lilies and Lavender, and the world beyond recedes to infinity, and we are carried back in thought to the stately days of the distant past, to monastery enclosures, and the pleasures of the fair. I do not think there is a flower in any garden, be it old or new that exercises quite the potent influence on the senses that the Madonna Lily does. To-day, just as it did several hundred years ago, according to a gardener writing in a time when all the S's were F's in printing, "A vast cluster of pure snowy white flowers, that wheresoever situated it distinguishes itself singularly ornamental, and diffuses a fragrant odour all around." It grows almost anywhere. In the old book referred to above it is recommended, together with the Martagon Lily, for "shady and close places the most eligible, for they will thrive under trees, and often in small gardens in the midst of buildings, in towns and cities." In light, starved soils, mungled with the roots of old hedges, on strong rich soil in the full sun, in soils impregnated with lime, and in places where time has removed the upper surface of the earth and worn it down to lime-tree soils, even in places where lime has to be added for the cultivation of most things, you will find the Madonna Lily thriving.

Like most things, however, the better the conditions the better the results. When the term Madonna was first applied to this Lily I do not know, but in most old gardening books it is simply called the "White Lily." There are several varieties in cultivation, and some in books that may or may not exist. One with purple stripes, another with variegated leaves, a sickly looking thing at the best, but which was evidently very popular at one time, as it was recommended to be "disposed alternately with the common white

Lily whose leaves are entirely green, that they will exhibit a more striking variety." There is also a double form that has lost its fragrance, and of the single there are two or more forms, only one of which is worth growing because it is in every way the best, and is known as the broad-petalled variety. The narrow petalled or star-shaped variety is quite common, and I think it must be of this that an ancestor of mine wrote some two hundred years ago as the "dependent white Constantinople Lily" and even then he did not think more of it than we do to-day.

Lilium candidum is best planted soon after it has finished flowering. August is not too early, but the planting can be extended well into the spring, if necessary, providing the bulbs have been kept sound, firm and fresh. The soundest policy is, however, to adopt the principle, "If 'twere done, then 'twere well 'twere done quickly."

The next two popular Lilies to be introduced to the garden should be *Lilium croceum* (Orange Lily) and *Martagon* (Turk's Cap Lily). The latter embraces various species and varieties, but of *croceum*, so far as the modern garden is concerned, there appears to be only one. With a bulb that seeds so freely we might have expected all sorts

of variations, through hybridising or natural phenomena—and, indeed, there do appear to be inferior or superior forms in cultivation—but no one has taken the trouble to perpetuate even the best of them as a selected form that I have heard of. It is also a curious fact that whereas Parkinson described *Lilium croceum* (anreum) as the "Golden Lily," Abercrombie in "The Universal Botanist," who wrote nearly 200 years later, omits it altogether, describing the "Orange Lily" as *bulbiterum*, of which he mentions four varieties.

To Abercrombie the Orange Lily was certainly *bulbiterum*, a different, and to the gardener, inferior plant to the true *croceum*, but then he describes a *Lilium superbum* that bears no resemblance to the *superbum* of to-day, although his *canadense* is correct enough.

Lilium croceum does not mind lime, will grow, like *candidum*, almost anywhere, and is often seen to better advantage in an old cottage garden than anywhere else. It should be planted as soon as the bulbs are ripe in the early autumn, but with this also the planting can be delayed if circumstances demand it. Once established it is best left alone for a few years.

GEO. DILLISTONE.

(To be continued.)

THE RAMONDIAS

THE genus *Ramondia* is a small one, but nevertheless it contains one of the most charming plants for the rock garden, being well adapted for planting in vertical fissures. The species referred

to is *R. pyrenaica*, which forms large flat rosettes of dark green leaves and produces in June a wealth of violet-purple flowers with a rich orange centre borne on stems 3 ins. or 4 ins. high. There is a white form known as *alba* and a rose-coloured variety named *rosea*. *R. serbica* has brighter-coloured leaves, and the flowers are a pleasing shade of purplish mauve.

Just now the seed on the *Ramondias* is ripe, and if collected and sown at once it germinates readily. It is, however, a slow method, as the plants make little progress during the early stages; but if the grower can wait two or three years, then seed sowing should be adopted. The seed is very minute, and it may be sown on pots or pans containing a mixture of peat and sandy loam. No covering is needed, just give the pot a sharp tap when sowing

is completed. The pots should then be placed in a shady cold frame and never allowed to become dry. When water is required the pots should be placed in a vessel containing enough water to reach the rims, the method

AMONG THE MOST STRIKING OF ALPINE PLANTS, RAMONDIA PYRENAICA.

of watering least likely to disturb the seeds. When the seedlings are large enough they should be pricked off in boxes or planted singly in small pots and kept going in cold frames until they are large enough to take their place in the rock garden.

Another mode of propagation is by leaf-cuttings. The leaves are broken off close to the plant and then inserted in moist, sandy soil and kept in a close hand-light until rooted. The *Ranondias* can also be increased by division. A number of young growths are often found around the base of an old plant, and these should be carefully removed. They will soon form nice plants if potted off singly and grown in a frame protected from strong sunlight.

When planted in the rock garden, a shady situation where the surroundings are cool and moist should be chosen. Vertical fissures or crevices between the rocks are ideal for them where they are planted on their sides in such a way that no moisture remains for any length of time around the close rosettes. If they are planted so that water accumulates in the crowns the foliage will decay, and often the plant will die. A peaty soil with a little sharp sand will suit them, and, when planting, care must be taken to ram the compost to prevent any vacant spaces or holes between the plants and rock. During the summer months the *Ranondias* enjoy plenty of water at the roots and, if we experience a dry spell of weather watering will be necessary. By making a few holes some distance behind the plants it will be an easy matter to get moisture to the roots. A north or east aspect should be selected for *Ranondias*. T. W. B.

THE OLYMPIC MULLEIN

THOUGH I have known and grown this biennial off and on for more years than I care to count, it is only this year that I have fully realised the stateliness and beauty of the plant; and I note with something like gratitude the distinction a few plants of it lend to a garden which is at present, in too many respects, a drought-afflicted desert. The plants in question are self-sown and have arranged themselves, relatively to each other, at various levels, as if they had some vegetable instinct for picturesque effect. Some of them have appropriated points of vantage among Thymes and Sedums on a set of rough steps leading from one level to another, not an ideal location for 4ft. Mulleins, but I had not the heart to dislodge them, and so there they stay. Under suitable conditions *Verbascum olympicum* grows to a height of 6ft. or 7ft., and some of mine are of that height, or near it. The stem in well grown plants is concealed for some 3ft. or 4ft. from the ground by handsome dock-shaped leaves, rough in texture, dark green, and intricately veined, which clasp the stem and fall one over another in successive tiers, not so close as the tiles on a roof, but after that fashion, the leaves of one tier alternating with those above and below. So copiously, indeed, is the plant furnished with foliage that it is difficult to see the stem even when you part the leaves to look for it. Regarded therefore merely as a foliage plant, this Mullein is strikingly bold and handsome, but what makes it a thing by itself is the branched candlestick of bloom which rises up in due time from the leaf-stock to give the plant its finish. From the thick cluster of leaves where the inflorescence begins, a central column shoots up to a height varying from 18ins. in small specimens, to 40ins. in the highest measured, along the length of which central rod, from bottom to top, are set,

so thickly as almost to touch, clusters of bloom-buds, the number of buds in the several clusters varying, with the strength of the plant, from five to perhaps a dozen. On any given day, in any

nothing in common with the dull yellow of gold, and that any candlestick which had its branches set at the Mullein angle of divergence would be bound to spill a deal of wax. Further, the

THE CANDELABRA-LIKE VERBASCUM OLYMPICUM.

given cluster, only one bud, or at most two, will expand into the full flower, a shallow platter of clear cennothera yellow, with orange anthers, measuring an inch and a half or so across. Thus you have a column of some 30ins. or 40ins. set with pretty buttercup saucers from bottom to top, the blooms, however, being sufficiently spaced to prevent that too solid appearance which seems a defect in the inflorescence of some Mulleins. If, however, the height of the central column were all, *V. olympicum* would have to yield place to *V. pannosum*; for near by the Olympics I find a flowering column of *pannosum* which measures a little over 50ins. But then the flower stem of *V. pannosum* is a solitary and somewhat too solid column, whereas in the Olympic Mullein there spring from the base of the centre shaft, at a somewhat acute angle, a forest of subsidiary rods (five, six, sometimes as many as eleven) each of more than respectable height, but always shorter by a head than the central rod and, like it, clothed loosely and gracefully throughout their length with soft-petalled buttercups. In this noble Mullein, therefore, at its best, you have a flower-head of exceptional size, of beautifully symmetrical design, and of a pure and rich colour—a many branched golden candlestick I was going to call it, but remember in time that the clear colour of the Mullein has

comparison would be a doubtful compliment to the flower, for it the branched candlestick of the Temple is faithfully represented in the Arch of Titus, as no doubt it is, the Mullein, in point of artistry at least, leaves that masterpiece of goldsmith work far behind.

In spite of July heats, possibly because of them, these Mulleins keep on, day after day, putting forth fresh flowers, while other biennials, such as Canterbury Bells, which give infinitely more trouble, flower themselves dead almost before you have had time to note their colours. My Mulleins began to shew colour a month ago, and, though now somewhat past their best, are still gay, their reserve of unexpanded buds giving every hope of yet another month of bloom. In gardening you must not be too ready to trust appearance. With *Verbascums*, at least, things are not always what they seem. You go out of an evening and regard your Mullein sadly, thinking that now at length, for sure, its glory is as good as gone, to experience, however, next morning all the relief of a respite, when you find the flower shafts are gay as ever, a flutter of fresh blossom along their whole length. Of course, the time comes when the clusters of bloom buds do begin to "peter out," and the distances between the flowers to lengthen; but the waning process takes many days, the plants

meanwhile retaining much of their beauty, until at last you have merely columns of closely set seed capsules, each containing an infinity of small seeds packed as carefully and with as watchful an eye to economy of space as if the welfare of the universe depended on Mullein seed. How many million millions of seeds my own dozen or so of plants may produce, should the harvest be good, is a question, of course, beyond my arithmetical, but sufficient, at least, I should think, if judiciously spaced, to plant the waste places of the two

Americas, if not of the two worlds—which contingency, were it only possible, how much more beautiful than it is now would the world then be. Futile speculation apart, however, it is a comfort to think that the automatic arrangements of this notable Mullein for securing its own well-being and the continuance of its race ensure at least for the garden where they grow, and that without any trouble to the owner, biennial generations of the plant for as many years as he is likely to require them.

SOMERS.

CORRESPONDENCE

PLANTING BEARDED IRISES.

THERE have been discussions in *THE GARDEN* as to the best time for planting Bearded Flag Irises, and some have advocated spring planting—in March or early April—while others maintain that the best time is in July and August after the flowering is over and before the autumn root

However, I do not want to reopen this discussion as to the best time of replanting, for no one with any experience of Irises would recommend planting them in the winter months. Yet in a Dutch bulb catalogue just received, under the heading of Rhizomatous (large Bearded Flag) Irises, it is announced that "the whole of these Irises can only be sent

their own propagation and transplanting—and though they must execute an order as desired, they should urge their customers to order early, so that the plants can be delivered in July or August, instead of encouraging the bad practice of late planting by refusing to send out Irises except from "October to April." My advice, therefore, is to order from firms who will deliver in August, and refuse to buy at all unless the plants will be delivered by mid-September at the latest. If for any special reason one wishes to plant in the spring, one must be prepared for the risk of some losses should the season be wet, and blame neither the grower nor the constitution of the Iris.—A. J. BLISS.

ROSA HUGONIS.

I HAVE a fine tree of this which was given to me by Sir Harry Veitch soon after its introduction. It is some 10 ft. high and as much through, and has been a thing of beauty since the second year after planting. Last year there must have been thousands of blooms upon it and it was quite as full of buds this year, but when the blooms were half developed in May, we had frosts which checked them and the greater part never opened. The land where this tree is planted is strong clay so that it is evident that this fine Rose will succeed on practically all soils, as your correspondent "North Wales" vouches for its well-doing on very light and even rocky soils. The pity is that some people plant this and *R. Moyesii* in ordinary rose beds, for which they are entirely unsuitable.—A. H. PEARSON, *Lowdham*.

TRITELEIAS.

I THINK the enclosed excellent picture of *Triteleia uniflora violacea* in the rock garden at Hallingbury, taken by that admirable garden photographer, Mr. R. A. Malby, may be of interest to many readers who only know the *Triteleia* as a rather inconspicuous and decidedly uninteresting little bulbous plant. The form illustrated is the rather more deeply coloured violacea, but even the typical *T. uniflora*, given a sunny corner and left undisturbed, will provide generous masses of milky white blossoms, which are very pleasantly scented.—N. H. P.

FOXGLOVE SUTTON'S PRIMROSE GIANT.

WE are interested in your correspondent "Somers" remarks on Foxgloves, published in our issue of July 21, especially with reference to our strain, Sutton's Primrose Giant. This was originally sent us by a customer in India a good many years ago now, and it certainly is not *Digitalis lutea* or *D. grandiflora*, but seems to be identical with *D. purpurea*, except in its colour. It comes perfectly true from seed and is a very attractive plant for border or wild garden. It is very difficult to get fertile hybrids of *Digitalis*. We raised a fine strawberry-red self-coloured one some time ago, but it would not give seed.—SUTTON AND SONS.

ON HANDLING CUT GLADIOLI.

OPENING Gladiolus spikes in the shade modifies the colouring. Bright shades and tints become delicate flushings and shadings, while delicate tints are "thinned" to the faintest tinges of colour or even become white. This is well known to experienced growers. In the case of hybrids producing intense shades of violet, purple, crimson and scarlet, as well as yellow and other bright colours, it is desirable that the brilliant colouring be preserved when the spikes are cut for decorative purposes. To ensure this result, place the vases in the early morning sun for an hour or two daily, preferably after renovation and renewal

TRITELEIA UNIFLORA VIOLACEA IN THE ROCK GARDEN AT HALLINGBURY.

growth begins. My own experience is that when they can be replanted at once, or within a short time of lifting, Irises may, in a good season, be planted in the spring without harm, but, if the weather is bad in April and May, are always more liable to be attacked by rot than August plantings. When, however, the plants have to be out of the ground for some time (as must be the case when bought from the grower), which may be from a week to three weeks, then the right time and the only safe time for planting is in July and early August, when the old roots have nearly finished their work and the new roots are not yet starting. The actual best time depends on the weather and soil conditions. The rhizomes are also at this time fully ripe and can be dried off for packing, not only without harm, but probably with some benefit, since in our climate Irises seldom, if ever, get the drying off that they do in their natural habitat. If an Iris has to travel for any length of time in a closed box, it must be packed dry or it will surely rot more or less.

out from October until April." And this is, I believe, the usual practice, not only of the Dutch, but of some English firms also. It is this practice that I wish to protest against, as it is calculated to do great harm. Though some of the plants sent out at such a time (October or later) may pull through and eventually recover (in about a year), from this unnatural treatment, it is very likely that many will succumb, or, any way, in their enfeebled condition, be liable to get crippled with rot, and be any thing but a satisfaction to the buyers.

Many correspondents, chiefly from America, have written to me regarding the bad condition in which their plants have arrived and sometimes complaining of the total loss of many plants through rot. In practically all cases the plants were sent in late autumn or in the spring. Such experiences are likely seriously to affect the popularity of the Iris. No doubt many, though inexperienced, send their orders late, or specially desire to have them sent in the spring. But the growers at least do know better—they do not wait till October to do

of water. As it takes about three days after cutting to bring the spikes into blooming condition, this should be allowed for in advance of the date of intended use.

One of the causes of the popularity of the *Gladiolus* as a decorative flower is the fact (Mr. Gibson notwithstanding), that it has no perfume. There are few flowers used for decorative purposes that are not distasteful to someone—particularly in closed rooms—either on account of personal preference or painful associations. When the pollen proves irritating to the tissues of the respiratory organs, as in the case of hay fever subjects, the anthers may easily be pinched out during the daily renovation, when the faded florets are also removed. This removal of the anthers is desirable in the highly coloured types referred to, where the shed pollen dulls the brilliancy of the petals on which it falls.—H.

PLANTS WITH LEGENDS.

I SHOULD like to thank J. P. (page 387) for helping me with some legends, and wonder if he knows two delightful little books, "Flower Legends," by M. C. Carey, published by Pearson, Limited; the other by Bertha P. Standen, published by Gay and Hancock. I am now busy getting the garden ready and where there are several varieties of a plant I intend getting two or three varieties so as to have a longer flowering season. Then there will be the labelling, with story printed on each label, so that the garden will be a greater pleasure to children.—AN OLD SUBSCRIBER.

THREE TREES IN ONE.

I ENCLOSE a photograph of a remarkable tree, or rather collection of trees. A fine specimen of the Common English Oak has two other trees growing upon it. In the centre is a Mountain Ash or Rowan (*Pyrus Aucuparia*), with several stems 20ft. high, the strongest of which is 6ins. thick. On the right of the picture is to be seen a Common

THE STRAIGHT SMOOTH GROWTH OF ROWAN AT CENTRE TOP; THE BIRCH TO THE RIGHT.

Birch which, owing to its slender habit of growth, is in a rather recumbent position; the photograph was taken on May 24 and the foliage of the Oak was not so much developed as the leaves of the other two trees. The seeds of the two subsidiary trees had no doubt been deposited on the Oak by birds and germinated among the decayed matter in the forks of the limbs of the Oak and most likely they derive their support from the sap of the Oak. The Oak is probably over 100 years old, having a bole 5ft. through; the other two trees growing thereon are of something like twenty-five years growth. The tree is growing at Fencote, Hatfield, near Leominster.—J. T. F.

LILIUM TESTACEUM.

THE note by "Claremont" in your issue of July 7, page 349, regarding *L. testaceum* proved interesting to me, for around the town of Camden, Maine, on the shores of Penobscot Bay, where I happen to be staying for a few days this latter end of July, several colonies of this beautiful Lily have been observed in bloom. In front of my bedroom window, in a border facing east and quite close to the sea are several spikes of flower about 5ft. tall, bearing from three to five flowers. If any misapprehension as to its hardiness exists this can be dispelled by the fact that here the glass frequently falls to 18° or 24° below zero, Fahr., during the winter. The protection afforded by snow cannot be relied upon, varying in some winters from only a few inches to about 3ft. in others. The plant appears to produce better flowers and foliage here during dry summers than if the summer happens to be a wet one. The fragrance is delightful and there seems to be no reason why this charming Lily should not find a place in every collection.—WM. H. JUDD, *Arnold Arboretum, Jamaica Plain, Mass.*

LILIUM GIGANTEUM IN THE EAST OF SCOTLAND.

NICHOLSON says of this King of Lilies, "hardy only in favoured spots in the South of England." It is long since I proved this statement to be fallacious, having met with single specimens of it in flower in various localities in Scotland. It was only the other day, however, that I got the treat of my life, when I came upon well flowered groups of it in the Wild Garden of the Edinburgh Royal Botanic Garden. Here, it is luxuriating under the partial shade of trees, where there is apparently abundance of moisture. It is the fact of these two conditions in combination that is evidently the secret of success with this noble flower. Lovers of Lilies, please take note.—CALEDONIA.

BAD LABELLING.

IN your issue dated July 21, page 372, under the heading "New and Rare Plants," you say "Carnation (Border) Mrs. Groom" was given an award presumably on account of its uncommon colouring. Being interested in Border Carnations, I nearly got trapped in the same manner, but noticing that the award was not by the Carnation Society made me look closer and I found a small, faint P in front of the word Border. My suspicions were confirmed on seeing Messrs. Groom's exhibit that this was a specimen of the Cross-bred Perpetual Border type, which up to the present has not been recognised by the N.C.S., for what reason, I suppose, they alone can say. Had "Mrs. Groom" been a Border variety I should certainly have purchased plants, not on account, as you suggest, of its uncommon colour, but for the perfect scent of the blooms, not a very usual addition to the type

exhibited. I have frequently heard remarks being passed as to the way the new plant cards are written and this evidently misled such experts as yourselves.—G. STANBRIDGE.

ROSE ALBERIC BARBIER.

IN one of the issues of THE GARDEN [last year you mentioned Albéric Barbier as a good Rose, but that it did not flower a second time. I enclose

A FINE WEeping STANDARD OF ROSE ALBERIC BARBIER.

a photograph of that Rose taken recently. It flowered fully as well last year at this time, and again in the autumn and has been admired by many gardeners. This year it is *not* blighted and smothered with aphids, as is the case with red Roses, such as American Pillar, Excelsa, etc. Is that because it has such glossy and healthy foliage?—EDWARD BLUNDELL, *Cirencester.*

[The more robust the constitution of a plant the better it resists disease and insect pests; Albéric Barbier has a magnificent constitution. Though William Allen Richardson has beautiful glossy foliage, aphides seem very partial to it.—ED.]

THE MARSH GENTIAN AND A RELATIVE.

A PILGRIMAGE made a few days ago to a certain Welsh moor in a remote corner of which the Marsh Gentian (*G. Pneumonanthe*) flourishes, resulted in discovering that this much-discussed plant was not yet visible among the stubby heather in which it grows. I was, however, fully recompensed by coming across a great quantity of a very dwarf, large-flowered form of *Erythraea*—probably *E. littoralis*. This, at any rate, is what I took it to be. The short, peaty turf was dappled with the bunchy heads of pretty waxen flowers in a most beautiful rose-pink with yellow anthers. The individual blooms were about ½ in. across and they were crowded together on single or branched stems in dense pads of colour which were most striking in contrast with the tawny, sun-burned grass. These flowers, moreover, were most deliciously fragrant, and the fleshy, triangular leaves, more than ½ in. across, were not less green and succulent on the thin, sun-baked crusts of soil that covered the rocks than they were in moister places. I wonder if this exquisite little plant is in cultivation, whether it is perennial, and what success has attended its culture.—A. T. JOHNSON.

THE GOOSEBERRY SAWFLY

Of our garden fruits the Gooseberry has perhaps the fewest insect enemies, for there are only about five which are known to attack it seriously. They are: Gooseberry sawfly, *Nematus ribesii*, Scop.; Magpie moth, *Abraxas grossulariata*, Steph.; Capsid bug, *Plesioecoris rugicollis*, Fall.; the Winter moth, *Chematobia brumata*, L.; and the Spider mite, *Bryobia ribis*, Pagst.; and of these the first two and the last one are probably the most widespread. Where Gooseberries are grown beneath fruit trees, as in the orchards of Lincolnshire and Norfolk, capsid bug and winter moth sometimes attack them, though generally they prefer the Apple.

Since the writer has had several enquiries this season regarding attacks on Gooseberries by defoliating caterpillars, and on inspection these have proved to be the larvæ of the gooseberry sawfly, it is thought a general account of the pest and a discussion of control measures may be useful.

The adult sawfly, which appears about April, has four indescent, membranous wings with a distinct dark patch on the frontal margin of each fore-wing. The thorax is black and yellow and the abdomen is orange. In size the insects vary from about $\frac{1}{2}$ in. to 1 in. across the wings, the female being the larger of the sexes. The female is rather sluggish and does not take long flights, hence one area may be seriously infested with larvæ while a neighbouring one is absolutely free from the pest. The female possesses on the underside of her abdomen a pair of sawlike appendages, from which this group of insects derives its name. These minute saws are employed in making incisions in the leaf tissue of both Gooseberry and Currant and into these incisions eggs are fastened. The method adopted is as follows: The insect takes up her position on the leaf and, pressing her abdomen downwards, draws it forward under her, the saws coming into action and cutting the tissue. As the abdomen is drawn forward the egg is protruded and thrust along the incision, which is apparently held open by the saws; the saws are gradually withdrawn as the abdomen continues its forward movement and the egg is gripped by the outer membrane of the tissue, which closes together on the removal of the saws. The yellow elliptical eggs are laid on the underside of the leaves, generally along the veins, as many as thirty being laid on one leaf. The first illustration shews the eggs *in situ*.

The eggs hatch in from six to eight days and the young larvæ, which are apt to be rather restless, bite shallow holes in the surface tissue. As they grow they spread over the bushes and, feeding along the edges of the leaves, soon defoliate them. The larva has a black head and the body is greyish green with yellow bands behind the head and just before the tail. The upper surface of the body, except for a narrow dorsal line, is covered with black globular spots, from each of which a stout bristle arises. The "false caterpillar," as it is called, has three pairs of true legs, six pairs of prolegs and a large caudal proleg which, with the tail, is generally slightly curled. The larvæ are voracious feeders, and as John Curtis (*Gardeners' Chronicle*, Vol. I, page 548), says: "They go on feeding and changing their successive skins as they increase in size, until they are three-quarters of an inch long, when they are seen scattered round the edges of a partly demolished leaf, holding by the forelegs with their tails turned up or lying on one side." The feeding larvæ, if disturbed, readily fall to the ground and curling up in the herbage at the base of the bushes secure

some protection. When fully grown they moult for the last time and after a brief resting period the larvæ crawl down the stems and drop off the bushes and burrow into the soil, there to construct a light brown, tough, leathery cocoon in which to pupate. The depth at which the insects pupate

The back of a Gooseberry leaf, shewing eggs of the Gooseberry Sawfly.

Larva about its business of destruction (enlarged).

The adult insect (about four times natural size).

varies with the texture of the soil, but rarely exceeds 2½ ins.

The sawflies emerge from these cocoons in about three weeks in the case of the summer broods, but in the case of the autumn brood they remain as larvæ in the cocoons until spring, when they pupate, and the mature insects emerge in time to

oviposit on the young leaves of Gooseberry and Currant. There are often three broods per annum.

PREVENTION AND REMEDIES.

Miss Ormerod, in her "Manual of Injurious Insects," 1890, recommends the removal of surface soil from under the bushes in autumn or winter, and states, "For prevention of all attacks excepting what may be borne on the wing by stray sawflies blown from elsewhere, I believe the above plan to be most certain." She goes on to state, "This complete removal of the soil with the cocoons is quite worth while wherever Gooseberry caterpillar is prevalent; but, in case of the surface soil not being removed, a layer of unslaked lime well mixed with the soil as deep as the cocoons are, would be highly beneficial." Moreover, Miss Ormerod quotes letters from horticulturists who tried this means of control with a good measure of success. Recent work shows that good results follow the thorough forking over of the soil around the bushes in the autumn and in the spring and the burning of all prunings and rubbish. This can be done in small gardens; and in fruit plantations thorough working with cultivators between the rows in both directions in autumn and spring should be carried out, and in this case it is impossible to put too much emphasis on the destruction by burning of all plantation refuse. G. C. Gough, A.R.C.S., in the *Journal of the Ministry of Agriculture*, November, 1920, states, "A long list might be made of pests of garden crops which could be found in most heaps of unburnt refuse and which will ultimately find their way to the new crop unless destroyed. Regarding spray treatments, as the larvæ, when feeding, devour the surface tissue of the leaf and that is the portion to which sprays adhere, they can be destroyed by the use of a poison spray. This usually takes the form of lead arsenate paste at the rate of 1 lb. to 25 gallons of water, with a little soap or calcium caseinate as a spreader, or $\frac{1}{2}$ lb. per 25 gallons of water of the new "Super Arsenate," now being prepared by the progressive spray manufacturers. Spraying should be done at the first sign of attack and if necessary repeated later, though one spraying usually gives complete control not only of the sawfly, but of other leaf-eating caterpillars which attack Gooseberries and Currants.

HERBERT W. MILES.

Pterostyrax hispidum

The best examples of this tree we know of are in the neighbourhood of Cork and Queens-town, but mild climatic conditions such as they exist under there are not essential to their well-being. Near London it is entirely hardy, and flowers freely both at Kew and with Miss Willmott at Warley in Essex, although it is not likely to grow so large there as it does in the West, where it makes a wide-spreading tree 30 feet to 40 feet high. The pure white, fragrant flowers open in June and July on pendulous panicles 6 inches to 9 inches long, that hang in a row beneath the branches, one from each joint. The tassel-like appearance of the flower is due to the deep cutting of the corolla and to the protruded stamens. We know of no more interesting and striking object in the July garden than a specimen of this tree carrying its hundreds of graceful panicles. The curious fruits are spindle-shaped and covered with pale brown hairs. This tree, a native of Japan and China, is sometimes called *Halesia hispida*, but it is very distinct from the North American *Halesia*, of which the Snow-drop Tree is so well known a representative. It may be well to mention that *P. hispidum* is frequently offered in the trade with the specific name of "corymbosum."

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Spinach.—A good breadth should be sown, selecting the prickly or winter variety. Sow thinly in lines 15ins. to 18ins. apart. When the young plants are large enough they should be lightly thinned. Slugs are usually troublesome and these should be held in check by an occasional dusting of lime and soot.

Leeks.—The main crop will be ready for a little soil to be placed around the stems. If the roots are dry, a thorough soaking of water should be afforded a day or so before the operation begins. A light sprinkling of a reliable fertilizer will prove beneficial.

Potatoes.—Continue to lift this crop as the haulm begins to turn yellow and wither and, to save further labour, they should be graded at the time of lifting.

Peas.—The late Peas are growing freely and care should be taken to prevent the haulm being infested with thrips, especially during a spell of dry weather. If necessary give the roots a good watering and syringe the foliage with a reliable insecticide.

Brussels Sprouts.—Where early buttons are required, a sowing of Exhibition or Strymger's Giant should be made on a sheltered border. The plants may remain in the seed bed throughout the winter and then be transferred to their final quarters early in the spring. If time and space permit, however, a few seedlings should be pricked out in nursery beds directly they are large enough to handle. Brussels Sprouts enjoy a long season of growth.

Cauliflowers.—Where a supply of vegetables is essential and, moreover, as much variety as possible is needed, the Cauliflowers should be included, and seed sown about this date will produce fine heads next June and July when they are in demand. Two sowings are recommended, one about this date and another in September; probably the latter will give the best results. First Crop and Magnum Bonum are both excellent varieties. Select a sheltered open border and sow in lines 1ft. apart and, if the soil is dry, give the drills a thorough watering a few hours before sowing the seeds. When the seedlings are large enough, prick them out in nursery beds or a cold frame, but it should be borne in mind that they should be fully exposed to the air at every opportunity. They will need transplanting next February or March.

The Flower Garden.

Violas.—Some of the plants should be cut back in order to encourage basal growths suitable for cuttings, which may be inserted in sandy soil two or three weeks hence. A cold frame should be employed, where they will remain until next spring. Grow the plants hard by admitting plenty of air. In this district they do well in the open ground, no frames being required.

Hollyhocks.—It is often recommended to sow Hollyhock seed in February, but now is also a suitable time to perform this operation. A good strain should be secured and the seed may either be sown in the open ground or in a cold frame. If the latter is chosen, plenty of air should be admitted at all times. Thin sowing is essential, and if the plants are too thick a number should be removed and pricked out in the reserve garden.

Coleheiums.—During the autumn months C. autumnale produces a fine effect in the grass close by the rock garden, and from now onwards is a suitable time to plant the bulbs. Informal groups are recommended. A batch or two in the rock garden is also advised, and the plant is not particular as to soil.

Bulbs in Grass.—Daffodils, Tulips, Scillas, Snowdrops, Crocuses, etc., are so beautiful when naturalised in grass that a thought should be given to this phase of gardening and the bulbs planted directly they can be secured. They produce a wealth of bloom when established, and increase in numbers; moreover, they are no further trouble when once planted.

Lobelias.—The single varieties are easily raised from seed, but the double-flowered forms are increased by means of cuttings taken in the spring. It is necessary, however, to keep a few stock plants during the winter for propagating purposes, and to this end a few specimens should be cut back now, and then lifted a few weeks hence. Pull them to pieces and either pot them off or set out in boxes containing light sandy soil.

The Hardy Fruit Garden.

The Fruit Room.—It is always advisable to give the fruit store a thorough cleansing at this period, in readiness for the crop to be gathered later on. Stages should be scrubbed and walls lime-washed, afterwards admitting all the air possible for several days. I am afraid the Apple and Pear crop is a poor one, so it will be necessary to take extra care of any fruit that may be available. Some of the early varieties of Apples will need picking, and they ought to be disposed of before they lose their flavour. For dessert purposes many are best when freshly gathered from the tree.

Black Currants.—These should be pruned directly an opportunity occurs, but young bushes will not need much attention beyond cutting out a few of the weakest shoots to prevent them from being overcrowded. Other examples that have been planted for several years are producing a number of basal growths; these should be encouraged, and where necessary the older wood should be removed to allow the new shoots to develop. Where the bushes present a worn-out appearance, it is a good plan to cut them down to the ground level, as they often furnish plenty of new wood in consequence.

Fruits Under Glass.

Strawberries.—The plants to be used for forcing should be placed in pots 6ins. in diameter. Arrange three or four potsherds in the bottom over which lay a little loam fibre. The rooting medium should consist of the best fibrous loam three parts and one part manure from an old mushroom bed. A sprinkling of bonemeal and old mortar rubble may be added. Careful watering should be the rule and, for the time being, the plants should be stood on a bed of ashes outside.

T. W. BRISCOE.
(Gardener to W. R. Lysaght, Esq.)
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Onions.—The preparation of the ground for autumn sowing should be completed as soon as possible, because it is advisable to sow the seed about the middle of this month. Liberal manuring and deep cultivation are essential to the production of a good crop of Onions. Tread the ground with the feet and smooth it with the rake, after which draw shallow drills 12ins. or 15ins. apart; sow rather thinly. Trebons and Strasburg are two excellent varieties for this sowing.

Cabbage.—A sowing of Cabbage should now be made and the resultant plants allowed to remain in position over winter and be planted out in spring. If an early variety such as Early York is sown, and also some Winningstadt, a succession will be secured.

Cauliflowers.—A sowing should also be made of these and the resultant plants transferred to a cold frame in due course. Here again, in order to secure a succession, two varieties should be sown; an early variety such as Snowball or Early Erfurt and Veitch's Autumn Giant or Walcheren.

Parsley.—If a light of a cold frame can be spared and a sowing of Parsley is made in it, it will furnish a supply throughout the winter, independent of climatic conditions.

Vegetables Under Glass.

Cucumbers.—If the heat is declining in the Cucumber frame it should be maintained by means of linings; these may either be composed of fermenting materials similar to those of which the hot-bed was originally formed, or grass mowings may be employed. In the latter case it will be sufficient to arrange them on the top of the hot-bed close up against the woodwork, which for the short period it will not materially affect. Continue to regulate the shoots and pinch laterals, leaving one joint beyond the fruit. Do not allow surplus fruits to ripen unless it is intended to save seed, in which case one fruit will furnish sufficient seed.

Tomatoes.—Continue to feed plants that are swelling their fruits. Weak applications twice a week are better than strong doses at less frequent intervals. Pinch out all lateral shoots as soon as they appear. If it is intended to save seed, select full-sized, shapely, ripened fruits. Skin the fruits and carefully crush them in a fine strainer and there wash the seeds clean, after which place them on a tray and thoroughly dry them before sorting in a cool, dry place.

The Hardy Fruit Garden.

Strawberries.—Runners which were layered either in small pots or in turf squares should now be planted without delay. The ground having been duly manured and trenched or double dug (bastard trenched), the plants should be carefully lifted and planted with the aid of the trowel, the balls of soil knocked out of pots being left intact. Allow from 2ins. to 2½ins. between the lines, according to the vigour of the variety, and allow 15ins. between the plants in the lines. As soon as the fruit has been all picked off established plants the nets should be removed and stored, care being taken that they are perfectly dry before doing so. Plants that are to be trenched down in the near future will require no attention beyond the removal of any coarse weeds. Except those from which runners are to be taken, all the plants should be entirely denuded of runners and the soil thoroughly stirred and cleared of weeds by means of the Dutch hoe.

The Flower Garden.

Roses have hardly come up to the standard this year, and they have been about three weeks late; this means that the autumn crop of bloom will also be late, so all available means should be employed to assist the plants. Check greenfly with tobacco powder or a solution of soft soap; if mildew appears, spray with sulphide of potassium. Promptly remove all suckers and give the beds or borders a light dressing with sulphate of ammonia or superphosphate, after which stir the soil to a depth of from 3ins. to 4ins. either with the fork or the Buco cultivator.

Sweet Peas will now require rather more stimulants to maintain them in vigour; it is also very important that all spent blooms promptly be removed. Give additional supports if the plants have outgrown the original ones. Now is the time, while the flowers are still true to character, to make a note of any varieties that are to be discarded, and of any novelties seen which it is decided to include in next season's collection.

Sweet Violets.—These should be kept clear of weeds and all runners trimmed off as soon as they appear. The plants should on no account be allowed to suffer from lack of water and if thrip or red spider attacks the plants, suitable antidotes should be applied. Spraying the plants with pure water through a fine spray each evening for a time will generally clear them of red spider, and tobacco, either in the dry form through a puff ball or in a weak solution through a spray, is generally an effectual remedy.

Hedges.—Evergreen hedges should now be pruned without delay to enable the plants to form young foliage before the advent of winter. Holly and Portugal Laurel hedges should receive attention first. Evergreen Privet, if pruned too early, makes too much growth before the end of the season, the aim should be just to restore the evergreen character of the plants and no more. Bay Laurel hedges are best pruned with the pruning knife in spring.

CHARLES COMFORT.
(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian.)

GREENHOUSE AND CONSERVATORY.

Cyclamens.—Seed should be sown some time this month to provide plants for next year. The seeds are best dibbled in singly about half an inch apart, as they generally germinate somewhat irregularly. This method allows the more advanced seedlings to be removed without disturbing the others. The seed pans should be stood in an intermediate temperature and kept shaded until germination takes place. When large enough to handle the more forward seedlings should be pricked off into pans containing light, rich soil, and, later, may be potted off singly into small pots, or they may be left in the pans over the winter, potting them off early in the New Year.

Fuchsias.—A few stock plants of the desirable varieties should now be partly pruned back and placed in a house where they can be kept fairly warm and moist; under such conditions they soon start into growth. The young growths, when about 3ins. in length, should be secured as cuttings. It is very essential that this young fresh growth be obtained, as the resulting plants grow much more freely. Cuttings inserted towards the end of the month or during September should, when rooted, be grown steadily on, and in nine months should make plants some 8ft. in height. Such plants if kept well fed last in flower for a long time and are very useful for furnishing the conservatory beds towards the end of summer. Such plants should be allowed to grow straight on without stopping the leading shoot. If standards are

required, all lateral shoots should be rubbed out as they appear, and the leading shoot pinched when the desired height is attained. It usually takes several years to get large, well furnished heads for standards.

Aristea corymbosa. This beautiful blue-flowered plant is a native of South Africa and belongs to the Iris family, and is probably unique in having a hard, woody rootstock or stem. It has always been regarded as being a difficult plant to propagate successfully. Cuttings should be inserted some time during this month and are best secured from the base of the plant, detaching them carefully with a portion of the woody stock attached. The cuttings should be dibbled into pots containing sandy peat and stood under bell glasses in a cool greenhouse; in short, they should be given the same treatment as that afforded greenhouse Heaths. The cuttings usually take about six months to root, after which they should be potted off singly into small pots, using a compost of fine sandy peat. In their subsequent shifts a rougher compost should be used, adding a little light loam to it, and enough coarse, clean sand to keep the whole open and porous.

Hæmanthus Katherinæ and the hybrid *H. Andromeda*, as they pass out of flower, should not be neglected as is too often the case. The former, although a native of tropical Africa, succeeds quite well in an ordinary greenhouse, except when making its growth. After flowering, water should be gradually withheld as the foliage dies down, keeping the plants dry during winter in a warm greenhouse. This species is very fine if it can be planted out in a bed or border in a warm greenhouse.

Veltheimia viridifolia, which has been kept dry during the summer in a cold frame, should now be well watered and started into growth. If the plants are in good condition at the root it is not necessary to repot them each year. If repotting is necessary it should be done at this time, shaking all the old soil away and cleaning the base of the bulb of all dead and decaying roots. After potting, water should be very sparingly given until the plants have started into growth and have made a quantity of new roots. This plant only requires cool greenhouse treatment at all times, and can be increased by means of the offsets made by the parent bulbs. Stock can also be raised from seed and the young seedlings should be grown on without drying off until they attain flowering size.

Bravoa geminiflora.—This beautiful bulbous plant is a native of Mexico and, in the south, is hardy in sheltered borders if planted at the foot of a warm wall. In such a position it has been in flower for some weeks now. It is easily increased by means of offsets or seeds. The latter should be sown as soon as they are ripe. It is a charming plant for the unheated greenhouse, growing freely in any good potting compost. Dry roots can be purchased during the winter.

Canarina campanulata is a very quaint and pretty greenhouse plant which is worthy of more general cultivation. This plant is easily raised from seed, while the tuberous root stocks can be purchased dry during the winter. They should be potted up and started into growth early in the New Year. J. COULTS.

Royal Botanic Gardens, Kew.

A Charming Campanula.—One of the most delightful of the mid-season Campanulas of the rock garden is *C. arvensis*, once known as *C. acutangula*. This is a frail, semi-prostrate little plant whose slender branches, radiating from a modest central tuft of rounded leaves, terminate in a succession of purple stars to the width of nearly an inch. Though it is said to be a moraine plant, *C. arvensis* will prosper on a cool, well drained ledge, where it will not suffer from excessive wet in winter, and it appears to have a decided liking for limestone. The flowering season, which opens about the middle of July, extends to the approach of autumn.

Buddleia nivea.—The discovery and introduction from China of the many new forms of *Buddleia variabilis* have given a new importance to this group of shrubs, and a notable addition to the attractions of the garden in late summer. But not with them will *B. nivea* come into competition. The flowers themselves have little or no beauty; they are purple, but only the tips of the petals show, the rest of the flower, the calyx and the

flower-stalk, being embedded in a thick, soft, snowy white wool that also covers the young branchlets and the lower surface of the leaves and gives to the plant its chief interest. Like other *Buddleias*, this needs a good loamy soil.

Northern Trees in Southern Lands, by E. H. Wilson. Reprinted from the Journal of the Arnold Arboretum, 1923.—A year or so back Mr. Wilson made a long tour of investigation in Australia, New Zealand and South Africa on behalf of the Arnold Arboretum. One of the subjects which most interested him was the growth of exotic trees in the southern hemisphere, and this invaluable pamphlet is the result. It is amazing how much the Antipodes have to depend upon imported timber for their supplies of soft wood. In Australia there are no indigenous soft woods of any commercial value, while in New Zealand their native conifers are of slow growth and it has been found better to rely upon northern trees for reforestation purposes. Mr. Wilson found that *Pinus insignis* or *P. radiata*, whichever name you give it, is probably the best all round timber tree for the Antipodes. Yet this is odd, for in its native country (California) it is of little merit, its growth slow and the quality of the timber poor. This is what Mr. Wilson says of its performance south of the line: "In short it yields cheaply and quickly a class of timber necessary and in great demand in all these lands. The rapid growth and usefulness of this tree is now an established fact in the Antipodes." In New Zealand the Larch seems to be one of the best trees for growing in quantity. In the valleys and plains it is severely handled by frost, but on the mountain slopes it grows splendidly. In a land so mountainous as New Zealand there must be countless acres available for Larch plantations. Another good timber family which apparently has so far been rather neglected is the *Cupressus*, and of it Mr. Wilson remarks: "For forest planting the *Cupressus* as yet have been scarcely employed but the fact that their wood is very lasting and therefore most suitable for fencing makes them valuable." Northern hardwoods are not so satisfactory, or indeed necessary in the Antipodes, for in Australia the gums supply all ordinary hardwood needs, and in New Zealand they grow better than northern hardwoods. In certain places individual trees do well, as for instance *Salix babylonica* in South-Eastern Australia. But for those who are interested in this subject my advice is to get this pamphlet and read it for themselves, for it is full of meat.

Royal Horticultural Society's Gardens Club.—The annual meeting and outing of the R.H.S. Gardens Club took place on Saturday, July 21, when, at the kind invitation of Messrs. Sutton and Sons, the extensive seed grounds of that firm at Langley were visited. The trials could hardly have been seen at a better time, for most of the great breadths of annuals which are so well cultivated here were at their best and presented a magnificent spectacle of colour. Many new and improved varieties not yet in commerce were pointed out and much admired. The great advantage of autumn sowing for some kinds was very effectively demonstrated. The members of the Club, numbering about fifty, were conducted round by Mr. Noel Sutton and Mr. A. P. Balfour, who is in charge of the work at Langley. After lunch, at which Mr. Noel Sutton heartily welcomed the Club on behalf of his firm, a pleasant journey was made by road to Reading. The members were then conducted through the large range of glasshouses and the very comprehensive trials of flowers and vegetables in the open by Messrs. W. F. Giles, E. R. Jones, F. C. Eady and other members of the staff. Mr. Leonard Sutton presided at tea and again welcomed the party

Dr. F. V. Darbishire, the president of the Club, suitably expressed the Club's great appreciation of Messrs. Sutton's kindness and hospitality whereby the members were able thoroughly to enjoy a most pleasant and interesting day. At the meeting after tea Mr. C. R. Fielder, V.M.H., was elected president of the Club for the coming year.

FORTHCOMING EVENTS.

August 13.—United Horticultural Benefit and Provident Society's Meeting.

August 14.—Clay Cross Horticultural Society's Exhibition.

August 15.—Shropshire Horticultural Society's Exhibition (2 days).

August 18.—Highfields and District Gardening Society's Annual Show.

Answers to Correspondents

FLOWER GARDEN.

SWEET PEAS UNSATISFACTORY (T. G. F.).—The Sweet Peas are suffering from streak. This disease is due to a bacterial attack and is carried in the seed in many cases. The kind of cultivation given by our correspondent, i.e., the making of trenches and heavy manuring, while it helps the growth of the peas, appears also to lay them more open to the attacks of the bacteria. The use of potash manure may assist in keeping the disease in check. This should be applied in the form of sulphate of potash at the rate of 3lb. to the square rod.

MISCELLANEOUS.

PLANT FOR EXAMINATION ("Rex").—The specimen sent for examination is an abnormal fasciated stem of *Meconopsis Wallichii*. The fasciation is due to local conditions and frequently occurs in many plants. *M. racemosa* is quite a different plant.

PLANTS WITH LEGENDS (C. M. W.).—Trailing or climbing shrubs with legends are *Clematis Vitalba* (Traveler's Joy), *C. Viticella* and the White Jasmine (*Jasminum officinale*). Upright bushy shrubs with legends are the common Myrtle (*Myrtus communis*), Sweet Briar (*Rosa rubiginosa*), and Broom (*Cytisus scoparius*). A beautiful variety of the latter is *C. s. Andreanus*. Other good varieties of it are *C. s. Daisy Hill*, *C. s. Firefly*, and *Moonlight*. Broom (*C. s. sulphureus*). The Roses round which the old legends have been woven are *Rosa centifolia*, *R. damascena*, *R. alba*, Musk Rose (*R. moschata*), Moss Rose (*R. muscosa*). All of these are varieties of *R. gallica*, except the Musk Rose and *R. alba*. York and Lancaster is another variety. If our correspondent wishes for pretty representatives of Roses in the colours mentioned, red varieties are Hugh Dickson, Crimson Chateaux, Richmond and Gen. McArthur. White varieties are British Queen, F. K. Druschki, Mrs. H. Stevens and Candeur Lyonnaise. Yellow Roses are Golden Emblem, Souv. de Claudius Pernet, Christine and Golden Ophelia. The best Moss Roses are Common Moss (rose), Henry Martin (deep red), Blanche Moreau (pure white), and White Bath. The species of *Clematis* have already been mentioned. Modern and more showy varieties are Nelly Moser (mauve with red bar), Ville de Lyon (carmine red), Jackmanni superba (violet purple), and Lasurster (deep purple blue). The best forms of Honeysuckle (*Lonicera*) are Early Red and Late Red. The principal Veronica of the legends is *V. Chamædrys* or Germanander Speedwell. Beautiful garden representatives are *V. spicata* and *V. rupestris*. The Brooms represent *Cytisus*. Iris can be well represented by *I. germanica*, *I. g. Kharput*, *I. Cengialti*, *I. pallida* Queen of May, and *I. trojana*.

TENNIS LAWN UNSATISFACTORY (W. J. C.).—Our correspondent will not be able to do much in the way of improving the lawn till rain comes. Rolling before, and even after, would not be satisfactory. The grass always becomes coarse when it is neglected for a time. Cut it as closely as possible; uproot all coarse roots and weeds, especially the latter with taproots. Use an iron-toothed rake, vigorously scratching up the surface freely. Put on sifted soil to fill up hollow places and roll thoroughly when the ground is moist. When the first spell of dull, rainy weather comes sow grass seeds, in which mixture there should be 10 per cent. of Hard Fescue. Do timely rolling and not too much cutting, very low down, of the young grasses this autumn. With careful treatment in spring the lawn will, probably, be a very nice one.

NAMES OF PLANTS—C. A. W.—1, *Cynoglossum Wallichii*; 2, *Anchusa myosotidiflora*; 3, *Delphinium* seedling of little value.—A. H. H.—1, *Inula Heleum*.—R. M.—1, *Erigeron macranthus*; 2, *Cephalaria* sp. (cannot tell which without leaves); 3, *Gaura coccinea*.—E. C. B.—1, *Desfontainia spinosa*.—H. N.—1, *Escallonia chinensis*; 2, *E. laurifolia*; 3, *Potentilla fruticosa*; 4, *Alnus glutinosa*; 5, *Erigeron micranthus*.—G. B.—2, *Geranium pratense flore pleno*; 3, *Spiraea salicifolia*; 4, *Calceolaria integrifolia*. The Roses (Nos. 1 and 4) had fallen on arrival, thus making identification impossible.

S. M. WILMOT & CO., Ltd., BRISTOL.

The "PERFECTOR" ARCH forms an ideal setting for the Rose Garden. The man whose pride is in his Garden will appreciate the simplicity and effectiveness of this design. The construction is light, yet strong enough for a permanency, being specially designed for the cultivation of climbing Roses, Clematis, etc. It is made entirely of OAK and treated with Solignum, size 7 ft. high above ground level, and 3 ft. 4 in. wide inside. Price £1 each. Orders for three or more will be sent Carriage Paid. Cash with order. These can be made wider than 3 ft. 4 in. if required, prices for which will be quoted on application, stating number required.

THE
"PERFECTOR" PERGOLA.

This is constructed with the above Arches spaced any distance up to 6 ft. apart. The longitudinal and secondary cross bars to complete the Pergola are supplied in OAK, treated with Solignum, at 1 6 per foot run of Pergola; any lengths to suit your requirements. Thus the price of the Pergola illustrated, 25 ft. long, works out as follows:—

4 Arches at £1 each	£4 0 0
25 ft. run Top Bar at 1 6	£1 17 6

CARRIAGE PAID .. £5 17 6

State nearest Railway Station when ordering.

The Caterpillar Havoc

It grows generally had acted upon
the advice of the Ministry of Agriculture
last year, and Banded their fruit trees,
there is no doubt that much of the havoc
caused by Caterpillars this season would
have been avoided.

As it was, 1922 being a mild year for
Blight, many were induced to forego this
simple yet effective means of checking
activities of the Winter, March and
Mottled Umber Moths.

However, everything points to the fact
that Fruit Tree Banding will be much
more general this Autumn, and the most
important thing is to be sure that the work
is done in good time.

Winter Moth

one of the most harmful and widespread
of all fruit tree pests, is the first to put in
an appearance, and has often been noticed
during September, so that the work of
Banding should be completed by the end
of August, or as soon after as possible.
The Bands should be allowed to remain
until the time for renewal the following
year.

As each female Moth may be responsible
for 200 to 300 Caterpillars being hatched
out in the Spring, it will be appreciated
that as few of the Moths as possible be
allowed to reach the branches of the trees.

The Best Safeguard

Undoubtedly, the best and most reliable
material for the purpose is Stictite Tree
Banding Compound. It is far ahead of
the old-fashioned grease, being much more
effective from first to last.

Stictite is extremely "tacky," and one
application remains effective the whole
season. It will not "run" or dry up after
exposure, and it withstands the rain.

No. 2700.—VOL. LXXXVII.]

[AUGUST 18, 1923.]

THE SEED HARVEST AND AFTER

THOSE who harvest their own seeds will, by the time these lines are in print, be exceedingly busy. There are some plants which practically no experienced gardener troubles to raise from seed, though in all probability they seed freely. Spearmint, or as many cottagers aptly call it, "Peasemint" (*Mentha viridis*), belongs to this class. Speaking generally, plants which increase rapidly by stolons or underground "wires" offer little temptation to raise them from seeds, though seed-raising is, of course, the way to obtain new and better forms.

There are many biennial or monocarpic species of which, unless we save and sow the seeds—or, in certain cases, allow them to sow themselves—we shall inevitably lose the stock. Apart from these, there are many plants which are, in our climate, short-lived perennials. The existence of some of them may be prolonged by regular propagation, but it is to seeds that we must look to revitalise the stock.

Practically all the gorgeous Asiatic *Meconopsis* species are monocarpic, and the same applies to several *Enotheras*, including the common but very effective Evening Primrose of cottage gardens, (*Enothera biennis grandiflora*). Then we have the Queen of Saxifrages *S. longifolia*, and the quaint yellow-flowered *S. mutata*—both of which die after flowering—the Foxglove of our hedgerows (*Digitalis purpurea*), quite a number of the *Myosotis* clan, several *Silenes* and so forth.

Short lived perennials seem to be regarded from two aspects by the average gardener. Some of them he rightly treats as biennials and replaces regularly from seeds and these are not by any means always those of the shortest duration. The Wall-flower, for instance, on a wall or rocky ledge

is quite a long-lived plant and the same may be said of the Snapdragon (now fashionable as the *Antirrhinum*). Yet plants like *Lychnis alpina*, *Linaria alpina* and many *Primulas*, he is apt to treat as truly perennial and so to lose the stock. Some plants there are, like *Scabiosa caucasica*, which, perennial enough in some soils and situations, are of little more than biennial duration in other places.

Again, there is quite a number of plants which in Britain we advisedly treat as hardy annuals or hardy biennials, which in their native country are good perennials. Two plants of the great Poppy kindred come to mind in this connexion—the *Eschscholtzia* and the Horned Poppy (*Glaucium*).

Now, it is quite obvious that with these biennial, monocarpic and short-lived perennial species—to say nothing of the great family of annuals—a good deal of seed-sowing is essential to provide necessary replacements. Small wonder, then, that the average gardener finds little time for raising really perennial plants from seed. Nevertheless, the raising of

perennials in this way is one of the most interesting phases of gardening experience. A book might well be written on the best means of raising various plants from seed, but we scarcely know who would write it. As regards alpine seedling raising no doubt M. Henri Correvon of Floirac, Geneva, is the greatest authority, but his climate differs greatly from ours and climate makes a considerable difference to results.

The first question which arises is "What to do with our seeds when collected?" Shall we sow them forthwith or save them until early spring, or, at any rate, the turn of days? If we decide to postpone sowing until the New Year, shall we clean and packet them forthwith or preserve them in the pods until towards sowing time?

To these questions, it seems almost needless to point out, there can be no general answer, yet in the case of a rare plant, where experience seems to offer no guide, it is wise, if there is a fair quantity of seed, to sow it at twice—one portion as soon as it is ripe (or almost before), and the remainder in

early January. If there is but little seed available in such circumstances, sow it forthwith, even though doing so may entail great care in the dull days of winter to bring the seedlings through safely. If one has the misfortune to garden near a great and smoky city, of course, it is particularly difficult to winter tiny seedlings, and postponement of sowing is generally advisable.

There are certain genera of which the seeds lose vitality very rapidly if kept—*Meconopsis* and *Primula*, for example—and many others which, once the epidermis gets hard and dry, are slow to germinate even under the most favourable conditions. One would place *Gentiana* as a genus in this class. Beyond these of course there are seeds, such

THE RARE PINKISH MAUVE PRIMULA SINO-LISTERI.
Practically all Hardy Primulas should be raised from seed.

as the seeds are in a vacuum, protected by an oily wrapper which prevents them from germinating in any case.

With regard to the cleaning of seeds, we are strongly of opinion that where the seeds adhere in any way to their casing, cleaning is better left until towards the time for sowing, but, of course, many seeds free themselves from the seed vessels immediately they are mature. Seeds of alpine and hardy plants generally rapidly deteriorate if kept in a hot, dry place. A cool corridor or other place where a current of fresh air serves to prevent the growth of mould is an excellent place to keep home-saved seeds. They should be placed in bags amply large enough to contain the seeds and (if necessary) seed vessels and stalks and be looked over several times during autumn and winter.

Seeds normally slow to germinate will often sprout quickly and regularly if saved before becoming quite mature and *sown at once*. Never store immature seeds.

It is of the first importance that the seed-compost should be such as to suit the tiny seedlings when they germinate. The requirements of the adult plant known, it should not be difficult to provide a suitable seed-compost. Speaking generally, the following kinds of compost should suffice.

No. 1 will be suitable for the general run of herbaceous plants and will consist of good turfy loam, thoroughly rotted horse or cow dung and leaf-mould and, if the loam is at all close-grained, a little sharp sand. The texture of the loam will influence quantities—the idea is to get a porous, clean handling, but not “fluffy” medium, but six parts loam, two parts dung, two parts leaf-mould and one part (or less) of sand might be tried as a beginning, the whole to be rubbed through a $\frac{1}{2}$ in. riddle. Especially if the seedlings are likely to be any time germinating, a little broken charcoal or coke will be a useful ingredient. A proportion of old mortar rubble will be desirable for all but the very few herbaceous plants which object to lime. Pans, boxes or even pots may be used, but boxes are only suitable for seeds which germinate fairly quickly.

No. 2 may be called the stock alpine compost. It consists of two parts, approximately, porous ballast—small coke, broken potsherds or even brick—one part sweet turfy loam and one part vegetable matter—thoroughly decayed leaf-mould, or such mixed with an equal quantity of peat. This stock compost will suit most alpine found wild on granite or sandstone formations. For raising the very numerous chalk-loving species, limestone chips may be largely substituted for the ballast described above or, perhaps better still, a generous dressing of old mortar rubble may be incorporated in the compost.

The stock compost for American plants and Heaths we will call No. 3. This should consist of two parts decayed leaf-mould, one part peat and two parts turfy loam. All these composts will, of course, be passed through a riddle. Opinions differ as to the degree of fineness which is desirable and as to whether a layer of coarser material should be placed at the bottom of the pans. Our own view is that a $\frac{1}{2}$ in. riddle is sufficiently fine for ordinary purposes, but that $\frac{1}{4}$ in. sieve is useful for surfacing up pots for such fine seeds as those of *Erica* and also for covering purposes. Coarse compost beneath often means damaged roots at transplanting time. For specially saxatile plants, such as *Aethionema*, *Androsace*, *Encarnated* and *Kabschia Saxifragas*, the pans should be more than half filled with small coke or broken potsherds before the compost is put in.

Pans containing very fine seeds will, as usual, be watered from below. Larger seeds can be rosed overhead with the raining rose on a Haw's pattern can.

Perhaps it will be well here to mention a special compost (No. 4) for such moisture-loving plants as

THE HELIANTHEMUM COME READILY FROM SEED.

SCHIZOCODON SOLDANELLOIDES ILICIFOLIA.
The Schizocodons need care in their early stages.

VERY EASY FROM SEED, THE SNAKESHEAD, FRITILLARIA MELEAGRIS.

Pinguiculas and the bog Orchises. This is made from No. 2 by adding some additional vegetable matter—leaf-mould rather than peat—and a proportion of finely chopped live Sphagnum Moss. The moisture-holding properties of Sphagnum enable us to grow through all their stages in lowland gardens, plants not otherwise possible to cultivate.

At this season cold frames or pits with a northerly aspect will be the best place for our boxes and pans of seeds. The sun-loving kinds should, of course, be moved to a lighter place as soon as germination takes place.

The following table shews what the writer has found the best treatment for various of the more important families of perennials.

WHEN AND HOW TO SOW.

	When.	Compost.	Remarks.
Abies	A.	1.	
Acæna	A.	2.	
Achillea	A. S. . . .	2.	(Alpine species.)
Aconitum	A.	1.	Usually slow to germinate. Use sterilised soil.
Adenophora	S.	1.	
Æthionema	S.	2 & lime	
Althæa	S.	1.	
Alyssum	S.	2 & lime	
Anchusa	A. S. . . .	1.	
Androsace	A. S. . . .	2.	
Androsace (remainder)	A. S. . . .	2 & lime	
Andromeda	A. S. . . .	3.	
Anemone	A.	2.	Slow to germinate. A. Pulsatilla and some others like lime.
Antirrhinum (alpine)	A. S. . . .	2 & lime	
Aquilegia	A. S. . . .	1 or 2 . .	Germinate best if sown quickly.
Arabis	S.	2.	
Arenaria	A. S. . . .	2.	
Arbutus	A. S. . . .	1.	
Arctostaphylos	A. S. . . .	3.	
Arnica	A. S. . . .	3.	
Asperula	S.	2 & lime	
Asphodelus	A.	1.	Often slow.
Aster	A. S. . . .	1.	Perhaps unworthy the amateur's trouble.
A. (Alpine species)	A. S. . . .	2.	
Astilbe	S.	1.	Keep seed pans always on wet side.
Aubrietia	S.	2.	Very easy.
Azalea	A. S. . . .	3.	Not difficult.
Berberis	A. S. . . .	3.	
Bocconia	S.	1.	
Borago	S.	1.	
Buphthalmum	A. S. . . .	1.	
Calandrinia	S.	2.	Plenty of sun when germination takes place.
Campanula	S.	2 & lime	Generally easy.
Cardamine	A. S. . . .	4.	
Cerastostigma	A.	1.	Hard seeded and often slow.
Cheiranthus	A.	2 & lime	
Chrysanthemum	S.	1.	
Cistus	S.	1.	Do not sodden.
Clematis	A. S. . . .	1 & lime	
Convolvulus	A.	2.	Less easy than might be expected.
Coreopsis	S.	1.	
Cortaderia	A. S. . . .	1.	Easy.
Corydalis	A. S. . . .	2.	
Cotoneaster	A. S. . . .	1.	
Cratægus	X.	1.	
Crocus	A.	2.	
Cupressus	A. S. . . .	1.	
Cyclamen	A.	2.	Sow thinly.
Cynoglossum	A. S. . . .	1.	Water freely until germination.
Cytisus	A. S. . . .	1.	
Daboecia	A. S. . . .	3.	
Delphinium	S.	1.	
Dianthus (Alpine species)	A. S. . . .	2 & lime	
Dianthus (Carnations, etc.)	A. S. . . .	1 & lime	Transplant quickly.
Digitalis	A.	1.	
Draccephalum	A. S. . . .	1.	
Dryas	A.	2 & lime	
Echinops	A. S. . . .	1.	
Eremurus	A. S. . . .	1 & extra drainage	Sow thinly. Use deep pans or pots. Must not be transplanted for two or three years.
Erica	A. S. . . .	3.	
Eriogonum	A. S. . . .	2.	
Erodium	A. S. . . .	2.	
Eryngium	A.	2.	Seed often bad.
Erysimum	A. S. . . .	2 & lime	
Erythraea	A. S. . . .	2.	Easy.
Erythronium	A.	3.	
Euphorbia	A. S. . . .	2.	
Feula	A.	1.	Very slow.
Fritillaria	A. S. . . .	1.	Easy, but not quick.
Gaillardia	A. S. . . .	1.	Easy.
Galega	A. S. . . .	1.	Easy.

	When.	Compost.	Remarks.
Genista	A. S. . . .	1.	
Gentiana	A. S. . . .	2.	Slow to germinate, especially if not sown immediately it is ripe.
Geranium	A. S. . . .	2.	
Geum	A. S. . . .	2.	
Gillenia	A. S. . . .	1.	
Gladiolus	S.	1.	Good soil and a little heat.
Gunnera	A. S. . . .	1.	
Gypsophila	A. S. . . .	1 or 2 & lime	All Gypsophilas are lime-loving.
Haberlea	A.	3.	Very fine seeds.
Helianthemum	A. S. . . .	2.	Slight heat helpful.
Helleborus	A.	2.	Rather slow. Keep moist.
Hepatica	A.	2.	Rather slow.
Heracleum	A.	1.	Very slow.
Hesperis	A. S. . . .	1.	
Heuchera	S.	1.	
Hypericum	A. S. . . .	3.	
Iberis	S.	2.	
Ilex	X.	1.	
Incarvillea	A. S. . . .	1.	
Impatiens	A. S. . . .	1.	
Iris (Bearded)	A. S. . . .	1 & lime	
Iris (herbaceous)	A. S. . . .	1.	
Juniperus	A.	1.	
Kniphofia	S.	1.	
Lathyrus	S.	1.

THE BULB ORDER

III.—Miscellaneous.

CERTAIN qualifications seem desirable in those who are going to get the best possible out of their bulb catalogues. To begin with, it is necessary to be a bit of a Jack Horner. Then one must do one's best to avoid being a "moon-raker." It's not all gold that glitters. I have heard of fulsome descriptions that have deceived the very elect. Lastly, every one to some extent must be a garden Quackerwodger, ready to take hints, for every true member of our Fraternity is never too big to learn from the humblest brother or sister. This is my excuse for penning this series of "tips," about which may I say that I hope they will be found to be more reliable than those laboured selections of winners which are to be found in the columns of many of our daily papers. Daffodils have been dealt with. Tulips will form the subject of the fifth and last article for the simple reason that there is no particular hurry to plant them. I had to build my present rectory house. One day I happened to be talking to a bricklayer, Jesse Suff by name, on the subject of our favourite tippie. He summed up his views by saying, "I don't like any of your intermediates; give me beer or champagne." This article and the next will deal with some intermediates, only let me remark that Jesse's dictum on drink does not apply to bulbs. Hyacinths from their ancient standing naturally

come first, but I fancy the sales of varieties for bedding and planting out of doors are small to what they were in the hey-day of formal spring bedding. At any rate, I do know that the Hyacinth growers of Holland in the days immediately before the Great War were lamenting the decline in the demand for their wares. The following may be relied upon as being good for planting out of doors: White, L'Innocence and Mimi; Pink, Jacques and Lady Derby; Red, King of the Belgians and La Victoire; Pale Blue, Perle Brillante and Blondin; Deeper Blue, Grand Maître and King of the Blues; Yellow, City of Haarlem. I do not recommend any of the purples or mauves, but I have an idea that if the rich claret-purple Distinction were to be associated with a silvery-leaved ground plant or a variegated grass like the variegated Arrhenatherum bulbosum, one would have a combination at once pleasing and uncommon. Hyacinthus amethystinus, or as I once heard it called, "Amy-trust-us"—quite à la "Glory be to thee, John" (Gloire de Dijon), and "Alphonso, whiskey and soda" (Alonsoa Warscewiczii)—suffers from being such a near relation of the Dutch Hyacinths. It is frequently tucked away in a very inconspicuous manner at the bottom of a page or elsewhere, after the pages that have been given up to these ancient lords of the garden, but let me ask readers who know it not to hazard a dozen or two. Long after

the giant- are over, slender graceful little anemones gives us its pale blue flowers. They are a real blue and, as everyone knows, we are not overdone with this colour in our gardens. It is charming in tiny vases as a cut flower. It is not everyone who has a bit of thin woodland in their garden patch, but a fair number of people have a shady border where the occupants may live undisturbed for a number of years and of which the soil is light. This is the sort of place for two or three of the best *Erythroniums*—America beats Europe in her Dog's-tooth Violets. The handsome marbling of the foliage is a great asset to all the *Dens-canis* varieties, but the splendid *grandiflorum*, with its two or three gracefully poised Turk's-cap-looking, Guernsey-butter yellow blooms on stems rising to 22 ins. high surpasses them in importance and beauty. So, too, does a most lovely white of similar habit and size, of which I seem to have lost the name, unless it is a seedling. A third beauty is the deep cream or primrose *Hartwegii*. Lastly, we have that prince of the revolutums, *Johannsonii*, which provides large flowers of a deep rose-pink. Get these as soon as you can and plant at once. I attempted the above one year in pots, but they were a dismal failure, although I thought I had treated them in every way "according to Cocker." Should it have been "according to Gunter?" I have read that in some of the isolated parts of North America they still swear by the older authority. I was now going to suggest *Fritillaria aurea*, of which I have pleasant memories as being a very beautiful member of the *Fritillaria* family whether grown in pots in a cool-house or in the garden—but I am sorry to say I cannot find it in any catalogue. It comes from Asia Minor, so no doubt that accounts for its disappearance. From a garden point of view the disturbance there is "a regular nuisance."

Does everyone know *Allium sphaerocephalum*? It is a quaint looking plant—a more or less round, tightly packed head of claret-coloured flowers placed on the top of a rather thin wiry stem which is but scantily clothed with long narrow leaves—is my description from life. A clump in a border of perennials is striking. Last year, if I remember rightly, there was quite a run on it in Covent Garden for cut flowers. It is something quite out of the ordinary for vases. A flower which has no history behind it can never be quite as interesting as one that has. I have long wished to see the real saffron Crocuses—*Crocus sativus*—and I thought, when my good friend the Crocus king gave me some bulbs, selected the spot, prepared the ground, and planted them with his own hands, that my desire would be gratified; but, no! they have had two chances of flowering, and each autumn they have been a disappointment. Mine, too, came from Spain—the original western home of this plant of the East—but this availed nothing. Do the saffron bulbs that one can get from say, Messrs. Barr and Sons and elsewhere turn out any better? It is worth trying for the sake of learning all that one can about it. *C. speciosus*—also an autumn bloomer—is another recommendation. Good clumps look well anywhere, but perhaps it looks best in large masses in the grass. After *speciosus*, but after a long interval, come *Imperati*, *Sustanus*, *Sieberi* and *Tommasinianus*. Have you, my reader, all the four in your garden? One of our Treasury notes with the Daffodil water-mark will bring you at least a dozen of each to try. Having tried them the odds are you will want more, unless you share the prejudices of the Early Victorians and dismiss them as having "insignificant, but interesting flowers." If the larger Dutch hybrids appeal to you more than these, might I suggest as purples, *purpureus grandiflorus* and *Herald*? as whites, *Mary and White Lady*? as a silvery-mauve, *Dorothea* (syn. *Maximilian* and I think, *Blue Celeste*)? as a

striped variety *Pallas* or *Lucretia*? as one of uncommon rosy-lilac colouring, the rather small-flowered *Distinction*? but above all, the famous Dutch yellow? With plenty of this last, left

undisturbed from year to year, our gardens become to some extent living representations of the rich saffron robes of mythological gods and goddesses.
JOSEPH JACOB.

PENTSTEMONS FOR BORDER AND ROCK GARDEN

THESE are some seventy *Pentstemon* species, all natives of North America and Mexico. These include many beautiful and interesting kinds, all more or less valuable for the border or rock garden, besides the florists varieties, which are the product of such species as *P. Cobæa* and *P. Hartwegii*. As a whole *Pentstemons* are of easy culture, delighting in a good, deep, rich loamy soil, with ample drainage. With a good depth of soil, fairly moist and well enriched, excellent results may be obtained. Many of the smaller growing kinds, like *cæruleus*, *confertus*, *glaber* and *heterophyllus*, among others, are more appropriate for the rock garden on account of their neat habit. Although mostly hardy in selected positions, many kinds are severely tried in winter, so that it is always advisable to have a reserve stock in frames, especially of the rarer and more tender ones.

For the purpose of propagation, seeds of many of the species are easily obtained and, if good and fresh, will germinate quite freely. Young plants are also easily raised from cuttings inserted in sandy soil in a close frame or handlight about July or August, when cuttings of the half-ripened shoots root readily. In this way quite nice little bushes of such as *PP. heterophyllus* and *Menziesii* may be raised, and if kept in a cold frame for the winter will flower well the next season. The following is a selection of the most desirable and ornamental kinds, suitable, some for the rock garden, others for herbaceous borders or beds.

P. AZUREUS is a pretty species from California, free-flowering and dwarf in habit, growing about a foot high. The flowers are of a pleasing azure blue, with reddish purple at the base of the tube, while the leaves are of a glaucous hue. It flowers

continuously for some time during the summer months, and is best suited for the rock garden.

P. BARBATUS.—This is sometimes known as *Chelone barbata*, and is one of the best border plants. It is an elegant perennial, specially well adapted for grouping in beds or borders. From a procumbent tuft of shining leaves arises a graceful stem, often 4 ft. high, bearing rich scarlet blossoms that come in profusion for a long time. As well as being one of the most beautiful, it is also one of the easiest to manage. It may be freely increased by division, as well as raised from seeds, which it bears freely. There are several varieties of this species grown in gardens, one of the best of which is *P. b. Torreyi*. The best time for dividing the old plants is in early spring.

P. CÆRULEUS.—One of the earliest of the genus to bloom, this species is also distinct by reason of the charming light blue of its flowers, which are produced in dense panicles. In habit the plant is about 9 ins. high and the narrow leaves are glaucous. Treated as a biennial, it forms a pretty pot plant, besides being useful for planting out in a warm sheltered part of the rock garden. It comes from the plains of the Western United States.

P. CAMPANULATUS.—A variable border species from Mexico, with flowers of purple, pink and violet in varying shades of colour. These are produced in branching inflorescences on stems 1½ ft. to 2 ft. high, during summer.

P. COBÆA (the Cobæa-flowered *Pentstemon*).—In conjunction with *P. Hartwegii* and others, this species has played an important part in the production of a most beautiful and valuable race of border varieties of great decorative value and is well known. When well grown, *P. Cobæa* is a handsome plant, growing about 1½ ft. high, with large flowers

THAT SPLENDID FORM OF PENTSTEMON MENZIESII, KNOWN AS *P. SCULERI*.

varying in colour from pale and reddish purple to white. This plant is a native of Texas and is not quite hardy. Seeds should be sown in June, and the seedlings grown on quickly, receiving frame protection for the winter. They will be ready for planting out in a warm sunny spot in April.

P. CONFERTUS.—A low-growing plant, forming a mat of deep green leaves. This species produces in early summer numerous branching racemes of purplish flowers on stems 6 ins. high. It is an easily grown, hardy perennial, suitable for the rock garden. Of a better colour is the variety *cœruleo-purpureus*. Native of the Rocky Mountains.

P. CORDIFOLIUS.—A half hardy, sub-shrubby species of climbing habit, suitable for a warm, sunny wall. The stems are clothed with small ovate leaves and bear terminal inflorescences of bright scarlet flowers in June. It is a native of California and easily increased by means of cuttings.

P. DIFFUSUS.—A strong-growing border plant about 2 ft. high, with purple flowers in rather dense heads during the summer months. It may be raised from seeds or cuttings.

P. GENTIANOIDES.—Under this name are included all the florists varieties which form an important race of late summer and autumn flowering plants. Taken as a group they are as varied as they are valuable, and few plants can compare with them in the profusion of their branches of scarlet, violet or purple flowers of many shades of colour. For beds on the lawn or bold groups in the border they are most attractive. Their culture is quite simple, the most essential detail being a good loamy soil, enriched with cow manure. While they are not shade-loving plants in a strict sense, they most certainly have a preference for a cool spot. They may be propagated by means of cuttings in September when they will root freely in a little heat. If potted on as soon as rooted and kept in frames, they will make nice bushy plants, especially if stopped two or three times before the following spring. Varieties are very numerous as may be seen by the number offered by nurserymen who specialise in the plants.

P. GLABER.—This is a beautiful, dwarf and free-flowering plant, about 1 ft. high. The leaves are smooth and undulated at the margin, while the flowers vary from azure blue to light purple. It is best treated as a biennial and raised from seeds every spring. A good plant for the rock garden, it is found growing in poor arid soils and its native habitat in North America. There is a good rose-coloured form of this in cultivation.

P. HARTWEGII.—Frequently met with in gardens under the name of Newbury Gem, this is a very attractive plant with scarlet flowers of good size. It is a native of Mexico, growing at an elevation of over 11,000 ft. on the Tolmes Mountain, and is one of the easiest to grow either from cuttings or seeds. There is a good white variety of this.

P. HETEROPHYLLUS.—This is perhaps one of the most charming of all the dwarf kinds, forming a neat bush about 1 ft. in height, with narrow, entire leaves and twiggly racemes of clear blue or rose-flushed flowers. It is a good plant for the rock garden where it will prove quite hardy in a sheltered, sunny and well drained position. Plants vary very much in colour, and when a good blue variety is obtained it should be increased by means of cuttings. After flowering cut the plants back and secure the little shoots that follow. Strip these off with a heel and insert in sandy soil, when they will soon root. It is a native of California and flowers during the greater part of summer.

P. HUMILIS.—A pretty species from the Rocky Mountains, forming tufts of low foliage and bearing stems 4 ins. to 6 ins. high, topped with large flowers of a good blue shade. It is a valuable alpine plant, grows well in gritty loam and is quite hardy on a sunny ledge.

THE VERY DISTINCT *PENTSTEMON CONFERTUS CŒRULEO-PURPUREUS*.

ONE OF THE BEST AND EASIEST, *PENTSTEMON HUMILIS*.

P. ISOPHYLLUS.—A handsome, sub-shrubby species from Mexico, forming a bush 2 ft. to 3 ft. high and bearing throughout the summer months panicles of rosy-scarlet tubular flowers. It is worth a place in every garden and is easily propagated by means of cuttings and also produces plenty of seeds. It is known also as *P. triflorus*.

P. JAFFRAYANUS.—Also known in gardens under the name of *P. Roezlii*, this is closely allied to *P. azureus*. It is of shrubby habit, 6 ins. to 9 ins. high, with flowers of a reddish purple colour in June. A native of California.

P. LEVIGATUS is a strong-growing plant about 2 ft. high, with large foxglove-like flowers of pale lilac to white. It hails from the United States.

P. MENZIESII is a very variable species, some of the forms of which are ideal rock plants of dwarf,

shrubby habit, small foliage, and rose or lilac-coloured flowers. The plant known in gardens as *P. cristatus* (the true *P. cristatus* being a coarse-growing plant), is *P. Menziesii*, and this form is a good plant for the choice rock garden, being only a few inches high. This is a native of California.

P. OVATUS.—A strong-growing border plant 3 ft. high, from North-Western America, this has stout stems and azure blue to rosy-purple flowers.

P. RUPICOLA.—A charming little plant of shrubby habit only 2 ins. or 3 ins. high, with glaucous grey foliage and very large ruby-red flowers in early summer—a good plant for the moraine garden or rocky ledge. This plant is often sold and grown under the name of *P. Davidsonii*, a totally distinct plant, also of dwarf habit, with small lilac flowers. Both are natives of Western North America.

P. SCOTTII.—Sometimes regarded as a form of *P. Menziesii*, this is quite a distinct plant. It is of shrubby habit, forming bushes 2ft. to 3ft. across, and 1½ft. to 2ft. in height. The twiggy branches are well clothed with narrow leaves about 2ins. long and the whole plant bears a profusion of large, violet-purple flowers in May. It is an excellent border plant, quite hardy in light soils. In its

native habitat on the Rocky Mountains of Oregon it is usually found growing in rocky crevices. It is an easy plant to grow and propagate.

P. SECUNDIFLORUS.—Somewhat similar in habit to *P. glaber*, but the violet purple or blue flowers are produced in one-sided panicles.

There are several red-flowered species which are not included above. As a rule they are somewhat

difficult to manage. Among the best are: *P. Bridgesii*, 2ft. to 3ft. high, with bright scarlet flowers; *P. centranthifolius*, bright carmine flowers; *P. Eatonii*, rich carmine scarlet; *P. Murravani*, bright scarlet; and *P. puniceus*, with large funnel-shaped flowers of a rich rose red or vermilion colour, which grows to a height of 6ft. in its native country, Arizona. W. L.

AN AUGUST SHOW AT VINCENT SQUARE

IN view of the hot, dry weather and its being the holiday season, a large show was not to be expected at the Royal Horticultural Society's Fortnightly Meeting on August 8, but although it was indeed rather on the small side, there were plenty of good flowers in seasonable variety. New plants were much fewer than at recent meetings and in addition to those mentioned at the end of these notes there was an orange coloured *Calceolaria* from Lord Lambourne, in which the colour was good, but the blossoms small for the size of the plant, and Mr. W. F. Horne sent well flowered plants of the white *Nerium Oleander*.

Orchids were represented by a very small collection of *Cattleyas* and hybrids from Messrs. Cowan and Co. There were no novelties nor was there any fruit exhibit. It seems a pity that the Bunyard medals, which are offered at each meeting for different fruits, have met with such a poor reception.

Roses were of exceptionally good quality. Glorious stands of Betty Upchurch, Lady Inchiquin,

Sunstar, Isobel and Francis Gaunt were set up by Messrs. Alex. Dickson and Sons, who also staged Richard West, a new Hybrid Tea of butter yellow colouring and an apricot centre. It has a slight but pleasing fragrance. The Rev. J. H. Pemberton had a pleasant collection of Roses in which such free-flowering single sorts as Pax, Isobel, Mermaid and Vanity were most prominent.

Herbaceous *Phloxes* gave beautiful colours and refreshing fragrance. A large oval group on the floor in the middle of the hall, arranged by Mr. H. J. Jones, was the best exhibit, and was awarded a gold medal. His best sorts were Le Mahdi, Evelyn, Rosine, Etna, Miss A. Ellis and Frau Ant. Buchner.

Various other exhibits included good herbaceous *Phloxes* in their collections. Mr. M. Prichard also had the relatively uncommon white variety of *Agapanthus umbellatus* and some interesting *Montbretias*. Mr. W. Wells, Junr., shewed a good variety of *Scabiosa caucasica*. Mr. H. Marcham, a newcomer, had a quantity of a graceful *Scabiosa*

named Azure Fairy, a misnomer, but quite a desirable mauve-coloured variety.

In the middle of a group of border flowers Mr. Amos Perry had a number of fine spikes of *Lilium tigrinum plenum* of showy colouring. He also staged spikes of *Yucca filamentosa*, White Lavender and *Lythrum daleana*, a showy rose-coloured *Loosestrife*. That beautiful double pink *Hollyhock* Palling Belle was shewn in delightful quantity by Mr. F. G. Wood, who also had a couple of vases of *Dahlia Coltness Gem*, a dwarf bedding variety of brilliant colouring.

Quite a large collection of *Dahlias* was set up by Messrs. J. Cheal and Sons and their quality augurs well for the success of the National Dahlia Society's show next month. Their useful, decorative Star *Dahlias* included Surrey Star, Southern Star and Horley Star. The dainty little *Pompons*, *Collarettes* and *Cactus* varieties were also of merit. Among a collection of border flowers Messrs. Cheal placed happily a large vase of tall spikes of *Galtonia (Hyacinthus) candicans* bearing plenty of white bell flowers. Mr. J. Klinkert had a

THE STRIKING WHITE AND MAROON GLADIOLUS INCONTESTABLE IN MESSRS. LOW AND GIBSON'S EXHIBIT.

AN APTLY NAMED CARNATION—CHINTZ, ON MESSRS. ALLWOOD'S STAND.

CAMPANULA HALLI SHOULD BE A USEFUL ADDITION TO DWARF CAMPANULAS.

THE FRAGRANT NERIUM OLEANDER.

collection of topiary specimens, mostly in Box, which were well clipped.

There were several interesting collections of Gladioli. Messrs. Kelway and Son confined themselves chiefly to the large-flowered hybrids, but generally it was the daintier Primulinus varieties that found most favour. Major Churcher had two splendid seedlings. Nydia, of good typical form and delightful rose flushed shading, and Otranto, maize yellow with crimson lake markings in the throat and flushed with pale rose outside, were very delightful. In a large collection arranged by Messrs. R. H. Bath, Limited, there were Niobe, of brilliant orange shading; Hesperia, soft salmon;

and Arden, red tints. Messrs. Lowe and Gibson shewed many of their seedlings, including Salmon Beauty, Pansy, of quite uncommon colouring on the lower segments, and Altair, salmon-saffron, of the Primulinus section; and Montezuma, Red Fire and Incontestable, pure white with red blotch, of the large flowered hybrids. In the corner by the tea annexe Mr. Alfred Edwards had a well arranged group of Primulinus hybrids.

Carnations, as usual, were shewn in quantity and of good quality by Messrs. Allwood Bros. and Mr. C. Engelmann. Among the Fancy sorts, Chintz, Coquette and Circe were especially beautiful

NEW AND RARE PLANTS.

Anomatheca cruenta.—Though by no means new, this pretty little Cape Lily is much rarer than its merits warrant. It belongs to that numerous class of plants that are nearly, but not quite, hardy, so, although the bulbs will safely winter out of doors in an average season, in many gardens it is safer to lift them after the foliage has ripened and store until the following March. This species bears elegant scapes, about 9 ins. high, and carrying five or six flatish rich carmine crimson flowers, which have a dark blotch on the lower segments. It is eminently suitable for cultivation as a pot plant in the cool greenhouse, when it should be treated in the same manner as Ixias. Shewn by Miss F. Homfrey.

Buddleia nanhoensis.—If judged by the sprays on view this is practically a poor imitation of *B. variabilis*, but as a growing bush it is quite distinct and has much to recommend it. *B. nanhoensis* becomes a graceful spreading bush from 3 ft. to 4 ft. high and bears plenty of arched sprays of very fragrant flowers. The neat, broadly lanceolate leaves are pale green above and silvery underneath. Shewn by Mr. Clarence Elliott.

Campanula Halli.—A very free-flowering and quite dwarf little plant. It is a cross between *C. pusilla alba* and *C. Portenschlagiana*. From neat, rounded tufts spring, almost erect, widely expanded white, bell-shaped flowers of relatively large size. Award of merit. Shewn by Mr. A. J. Hall.

NEW LATE-FLOWERING WHITE TULIPS

FOR many years we had no A 1 late-flowering tall white Tulips. To be Irish, the best of them was White Swan, which is not late flowering at all, but a true mid-season variety of which once upon a time there would seem to have been so many. In old flower books of the seventeenth century, such, for example, as John Rea's "Flora, Ceres and Pomona" (1665), the mid-season or, as they were then called, the medias, were the largest section by far, while the serotinas or late-flowering ones were few in number. The exact reverse is the case with our present-day Tulips. We have, however, some mid-season varieties like *Coleur Cardinal*, *Le Réve*, the exquisite new primrose and lemon Canary Queen and the ancient stand-by White Swan. I wish it were the fashion of our modern lists to make a third section by restoring the "media" group to their dethroned place of honour. Themis, which is one of the three new whites, would, I think, be included in it. It is much earlier than either Carrara or Zwaneburg. As yet they are all three expensive, from about five shillings to seven-and-six a bulb, hence I would give Themis a miss until it comes down in price. It is not so very much better than a tip-top White Swan, and there is little to choose between them in their times of flowering. Carrara is usually classed as a Cottage variety, and is a pure white rather round-shaped flower with white anthers and pollen and a strong stem of about 2 ft. high. Zwaneburg is taller and its flower has the characteristic square base and build of a Darwin with black pollen. Is this black pollen an improvement or a detriment? The answer anyone will give is largely a matter of taste. If only the pollen would never shed when the anthers open, no powder patches could have been more becoming! But when wind or insect visits scatter the dark grains over the pure interior, the big camel-hair brush of the old Tulip enthusiast I feel ought to be requisitioned to give it a good spring cleaning. JOSEPH JACOB.

LOW-GROWING HEATHS

OF several hundreds of species of *Erica* the comparatively few species hardy in Britain are all European and many of them are indigenous to Britain. The dwarf species, about which these brief notes are written, comprise *carnea* (herbacea), *ciliaris*, *cinerea*, *Mackayi*, *multiflora*, *Tetralix* and *vagans*. To these we shall do well to add the Ling, *Calluna vulgaris*, so noticeable a feature of many English and Scottish moors and St. Dabeoc's Heath, *Daboecia polifolia*, the large-belled Heather of Ireland.

The earliest Heath to flower, *E. darleyensis*, is not a species but a hybrid between *E. carnea* and the tall-growing, but very valuable *E. mediterranea*. The plant is also sometimes known as *E. mediterranea hybrida*, and a plant with somewhat similar characteristics, but of a more erect habit of growth and probably representing the same cross as *E. carnea hybrida*.

Erica darleyensis is exceedingly free to flower and stray spikes may often be found with the bells fully expanded before Christmas, but its rather bluish mauve blossoms are generally at their best towards the end of February or in early March. The flowers usually go off a pinkish-lilac, very similar in tone to the newly-expanded blossoms of *E. carnea*, which itself dies a deep purplish-rose, that, though not specially objectionable, is perilously near to that of rotting flesh. A paler form of this plant called *E. carnea rosea* has no particular charms. In the pure white form, however, the snowy bells contrast well with the chocolate anthers, but this is less bold in habit than the typical plant and comparatively shy to flower.

The Scotch Heath, *Erica cinerea*, is typically a species with bright purple flowers which, at its best in June, continues to make something of a show until early autumn. The most noteworthy form of this is the practically scarlet *coccinea*, which is unrivalled in colouring by any other Heath. Rosy-pink forms are occasionally to be seen also, as well as deep purple and pure white ones.

Erica ciliaris is a species beautiful in flower and foliage, but it does not produce the mass of colour that some do. The relatively large flowers are rosy-red, the foliage greyish and the young growths hairy. The variety *Mawcana* is much superior to the type, the plant being sturdier, the flower larger and the foliage rich green. A very interesting hybrid is *E. Watsoni* (*ciliaris* x *Tetralix*), which partakes of the character of both species, but inclines upon the whole towards *ciliaris*.

The Cross-leaved Heath, *E. Tetralix*, is the commonest species of the genus *Erica* in Britain. This it is which provides such sheets of summer colour on the Welsh mountains. Despite the hint of magenta, the purple colouring of the typical plant is very fine in appropriate situations. There are two pure white forms, called respectively *alba* and *molis*. The latter has beautiful grey foliage, due to the presence on the foliage of a whitish down.

It is rather doubtful whether *E. Mackayi* is more than a form of the last named species, but it may be a hybrid between this and *E. ciliaris*. The blossoms are deep rosy-red. There is now a double-flowered form which has the advantage of lasting long in flower. *E. Stuartii* is another plant of the group which some think to have *mediterranea* "blood."

E. multiflora is to the eye of the gardener, rather than the botanist, much like *E. vagans*—next to be described. It is, however, more compact of habit. It is distinguished botanically by the anthers being merely notched at the top, whereas in *E. vagans* they are split to the base.

E. vagans is a very variable shrub, generally of lax spreading habit, but there are forms which approximate in growth to *E. multiflora*. To this more compact type belong the variety *Keyernensis* (St. Keyerne), with bright salmony rose blossoms. *E. vagans* remains long in bloom, though the progressive rows of seed pods militate against the beauty of the later flowers. There are pure white and more deeply rosy forms (*rubra*), all chocolate anthered, like the type and one called *grandiflora*, larger flowered, but even laxer in habit than the typical form (if there be such).

The unobservant will wander across the moors for many a day when the Ling is abloom and never notice any variety. It will come, therefore, as a shock to such to realise the great number of varieties actually in commerce, though these can actually form but an insignificant percentage of the forms in existence. The following should be in every collection of Heaths. *Alportii*, with blackish-grey foliage and rich crimson blossoms; *flore pleno*, with multitudes of fully double rosy flowers; *alba Serlei*, best of the white Lings, because so well furnished with vivid green foliage; and *aurea* and *cuprea*, both of small blossom beauty, but invaluable for the bronze and golden tintings of their

foliage. These two last are rather prostrate in habit; *flore pleno* is semi-erect and *Alportii* and *Serlei* are upright growers.

St. Dabeoc's Heath in its typical form has blossoms of some reddish purple hue, though some seedlings are very much richer in colouring than others. There is a pure white form and one called *bicolor*, which is, perhaps, more curious than beautiful. Here some of the bells are purple, others white, yet others striped and often a few sprays may be found in which red and white have combined to produce a delicate blush colouring, which form the gardener would gladly fix, were it possible, which, alas! it is not.

There is a form of this St. Dabeoc's Heath, white in blossom colour, which is, from the gardener's point of view, so distinct as to be worthy of specific rank. The bells are as large again as in the type, quite globular in shape and the habit of the plant is rather lax and spreading. This form is called *globosa alba*.

By crossing this with the typical reddish-purple *polifolia*, a series of globose forms may be obtained in many beautiful shades of pinkish lilac. There seems every probability that careful work on this plant might produce new and improved varieties which would place the *Daboecia* in the very forefront of Ericaceous plants. It is quite one of the showiest as it is.

THE JERUSALEM SAGE

PHILOMIS FRUTICOSA, usually known as Jerusalem Sage, is quite an attractive evergreen shrub and, being xerophytic, is a very suitable plant for dry or sandy soil or a warm sunny bank. Most gardens have such places and many other plants usually fail to thrive there. The *Phlomis* is a vigorous growing plant from 2ft. to 4ft. high, divaricately branched with stout square branchlets covered with grey branched hairs and large obovate to oblong rugose leaves arranged in pairs, also covered with hairs sparsely above, but thickly beneath, and giving the under surface a grey

appearance. The whole plant has the appearance of a giant Sage, so that even when out of flower it is quite ornamental as a foliage plant. During June and July it bears its bright yellow flowers, which are stalkless and arranged usually in two dense whorls from 2ins. to 3ins. across, each containing from twenty to thirty flowers. The corolla is two lipped, the upper one hood-shaped and pilose both inside and outside; the lower lip consisting of two large lobes at the front, with two small lateral lobes at the base and a few hairs on the underside. Like the majority of the genus it has a woolly ring inside the tube at the base of the stamens, the entire

THE BRIGHT YELLOW JERUSALEM SAGE, *PHLOMIS FRUTICOSA*.

flower being about twice as long as the five-angled, hairy, green, tunnel-shaped calyx. Surrounding the head of flowers are broadly ovate-lanceolate, hairy bracts with two pendulous floret leaves beneath.

It is a native of Southern Europe, chiefly Spain, Portugal and Sicily. Perhaps not hardy in all parts of the country, better results will be obtained, both as regards the length of life of the plant and the production of a profusion of blossom,

if it is planted in a position where the soil is distinctly on the poor side. Here at Cambridge it is perfectly hardy. This, no doubt, is owing to the dry climate. Every year it is covered with its bright yellow heads of flower and is quite as easy to grow as the common Sage, being easily propagated by cuttings. It is quite an old plant, having been cultivated by Gerard as long ago as 1500.

Botanic Gardens, Cambridge. F. G. PRESTON.

GLADIOLI IN VICTORIA

HAVING read with great interest various articles in *THE GARDEN* on the Gladiolus, it has occurred to the writer that a description of some of the best known of Victorian raised seedlings might be of interest to readers in England. The popularity which this showy and easily grown plant at present enjoys is, I think, amply proved by the fact that practically every grower for trade purposes of any standing finds it necessary, in order to keep up with the ever increasing demand for the corns, to include a very comprehensive list of Gladioli in his catalogue.

In Victoria the main centres both of seedling raising and distribution are Melbourne and suburbs, Ballarat and Camperdown. From Ballarat hails the celebrated variety Mrs. T. Rattray (raised by the late W. Rattray). I have not yet seen this,

but it is here generally recognised as the best rose pink on the market and must be very good to justify the high price asked for it. Messrs. R. Nicholls and Co. of the same city have raised a very large number of seedlings, some of the best of which are as follows: Jean Tenny, a huge flower of pale pink with yellowish throat; Egyptienne, a remarkable flower, described as "varying sunset colours," (in reality the ground colour is a pale sunset pink inclining towards lilac, flecked with slate blue and very slight suggestions of creamy yellow and white); Wm. Doncaster, a lovely flower of an unusual shade of salmon scarlet, with a neat yellow blotch; Bernice Rickey, much resembling Prince of India, but smaller and more intense in colour; and Clara Scott, a peculiarly coloured flower, described as rose cerise, but very lovely—it has a deep purplish-cerise blotch. Nerrina, light red, and Wm. Russell,

light purplish, are rather smaller flowers, but very decorative and the former is a very vigorous grower.

Messrs. Errey Bros. of Camperdown, where they are particularly favoured as to soil and climatic conditions, have raised a large number of excellent novelties, most of which have already become very popular. To mention a few of these: Chancellor, a splendid big dark crimson; Constance, a very bright and decorative orange salmon—a good flower for show, too, when at its best; Averill, a seedling from the popular Prince of Wales, a rosy-salmon, flaked salmon scarlet, with a yellow blotch, but varying considerably in flaking and intensity of colour, the former being sometimes absent, but in either condition a charming flower; and Herodion, also a flaked variety, rose pink, flaked carmine; it bears a considerable resemblance to and may possibly be related to Leolin, which, however, is slightly paler in colour and much less flaked—I have known it come almost pure pink without any flaking when grown in semi-shade, but both these varieties need to be well grown to do themselves justice, otherwise I find them rather disappointing. Eusign and Victor may be considered together, both are fine big scarlet flowers with large pure white blotches, sometimes a little flaked at the edge, the former is rather the darker in colour of the two and more liable to flaking. Eleanor stands out chiefly as a decorative and is one of the most vigorous and prolific "Glads" I know; the colour is a blend of cream, pink and

TWO PRIMULINUS HYBRIDS WHICH FLOURISH IN AUSTRALIA. THE ALMOST SCARLET ZENOBIA AND THE RUFFLED, ROSE AND GOLD LINTON.

deep rose, with a large crimson-maroon blotch in the centre. King Pearl is another big flower, pure white, deepening to creamy yellow in the centre, while Melvin is a vivid reddish-orange and makes a notable patch of colour anywhere. Perhaps the best of their seedlings to date—at any rate, as far as I know them—are Nimrod, Sentinel and Iremel. Nimrod is a huge flower of a very deep coppery crimson, flecked with chocolate, but this flaking so nearly blends with the ground colour of the flower as to give a self-colour effect; I consider it easily the best of the crimson shades. Sentinel is a splendid show flower, very large and bold and of a lovely warm salmon pink, with a crimson blotch on cream ground. Iremel is a very fine red, too deep in tone to be called scarlet, but too bright to be called crimson, though, if anything, nearer the former. It has a large deep cream blotch and makes a splendid companion flower to Ensign or Victor. The last I shall mention of Messrs. Errey's raising is Titan, aptly named, for the flowers are enormous, quite the biggest I know, and the colour very pleasing, clear salmon pink, lighter towards the centre, with a rather small purplish mark in the throat. In spite of its huge size it loses nothing in beauty, but of course it requires to be staked carefully as the spikes are so heavy.

Turning now to the primulinus hybrids, it seems that up to date Mr. G. H. Francis of the Oldown Nursery, Upper Hawthorn (a suburb of Melbourne), is the only grower to raise these hybrids to any extent. I have not seen a great number of his novelties, but the following are very good. Harmony reminds one of the well known Salmon Beauty, but is vastly superior both in size and colour, which is a lovely shade of pink, inclining to salmon, with a large blotch of yellow in the centre. The colours are wonderfully clear and pure. This and Lovelight are two of my greatest favourites. Lovelight is difficult to describe; the catalogue says "flesh, gold throat," but the colour is really a beautiful blend of pale flesh pink, cream, yellow and palest salmon shading to yellow in the throat, which is marked and dotted with crimson; the smoothness of the flower is quite remarkable, having the appearance of being modelled in wax. Treasure is a salmon pink flushed white, and Hope a pale flesh pink with a beautiful throat; both are very delicate in tint. Canary King, a very good yellow of fine form, and Lydia, yellow with crimson blotch, are as good as any of their respective colours. Those who are fond of queer shades will like Crescent, described as mahogany red, but really a shade of crimson with a decided suspicion of chocolate brown, each petal having a fairly broad gold stripe. Lena closes the list; it is a very rich shade of bright apricot and a splendid variety for decoration.

Before I leave what is to me a fascinating topic, I have a few more remarks which may be of interest. As to local conditions, the climate here (about 30° S.) is mild, with comparatively few frosts in winter, and Gladioli can be flowered with ease all the year round by planting in succession. Those which are flowered and have to complete growth in the colder months (roughly May to September) are not so satisfactory and do not produce such good corns for next season. This is, of course, what one would expect under the conditions. The majority are planted to bloom in autumn and so avoid the hot days (over 90° Fahr.) of summer, of which, however, only an average of twelve occur between December and March. In autumn, too, the colours are frequently purer and richer.

As to cornlets, many varieties seem always to produce but a very few frequently none at all, while others are almost always most prolific in this respect. Last year one corn produced an enormous new corn, over 10 ins. in circumference,

and over 140 cornlets, but this year another "beat it hollow" by producing two very large corns and considerably more than 400 cornlets!

Most varieties of Gladioli seed with great freedom, but a few varieties I find invariably produce very few seeds per pod, the most noticeable in this respect being Lavandula Major, Herada and Helios.

The varying opinions as to the "best dozen" as expressed by various readers in THE GARDEN during the early part of the year have been of much interest. Here are my selections, ranked in order of personal preference rather than of merit and exclusive of Australian-raised varieties, many of which take a very high place.

Primulinus Hybrids:—Myra, Alice Tiplady, Nydia, Salmon Beauty, Zenobia, Elbeton, Ulrica, Linton, Firefly, Arlon, Angola and Dexter. The first two are absolutely indispensable anywhere.

Large-flowered Varieties:—Byron L. Smith, Lavandula Major, Mme. Mounet Sulby, Herada, Mrs. Dr. Norton, Pink Perfection, Mrs. F. Pendleton, Orby, Flora, Britannia, Prince of Wales and Will-rink. Flora is an excellent substitute for Golden

Measure, inexpensive and scarcely inferior to that ridiculously high-priced variety.

Other excellent varieties which will give every satisfaction are Afterglow, Amaranth, Evelyn, Kirtland, Florence, Rouget de Lisle, Halley, Saphir, Liebesfluer, White Giant, Maréchal Foch, Meteor and Prince Henry of York (for colour), Captain Sverdrup, Pinnacle, Prince of India, Leonie, Loveliness, Damask, Europe, Emile Aubrun, Intensity and Helios. Varieties I have found disappointing are as follows: Captain Brandt, for form; Niagara and Yonell's Favourite for colour; and Beatrice Marion, for both.

I have as yet only grown a few of the ruffled varieties, but of these Rose Glory, Joe Coleman and Pride of Lancaster are excellent. Alton has not yet flowered and Orange Glory, though a lovely colour, is spoilt by usually having the blooms cramped—often to the extent of deformity. There is ample room for new introductions in this section as a good "ruffle" imparts a considerable amount of beauty and distinction to the flower.

Geeelong, Victoria, Australia.

AUSTRAL.

LATE WINTER AND SPRING-FLOWERING PLANTS

ALL lovers of beautiful garden displays must look ahead, very seriously, at least four times during the year. If cultivators did not make due provision in good time there would be a scarcity of flowers when there should be a profusion; these remarks apply to hardy border plants as well as to those grown under the protection of glass. Three plants, well cared for, are of more value than five that have been neglected. It is, of course, always harvest time with the gardener, but sometimes, like the miller, he must attend to many duties at once, so, along with the usual ones the garden calls for, he should pay special attention to the stocks of spring-flowering plants now growing in boxes, frames or nursery beds.

AUBRIETIA.—For massing and early spring blooming few plants are better than this. Old tufts cut back, divided and planted out have had a struggle to live in some soils during the recent spell of hot weather. The constant use of the Dutch hoe and occasional soakings with clear water have done much good and the tufts are now increasing nicely in size. From good strains seedlings look well this year and all those now in boxes should be planted out in nursery form so that fine specimens will be available for lifting in October.

POLYANTHUS.—I am sure many readers will have had trouble with their young stock and lost many old plants during the past ten weeks. Personally, I grow about two thousand seedlings each year and, had I planted all out in the usual border, many would have perished. Fortunately, I decided to form a special border in a favoured position and the young plants are now growing splendidly. They will be shifted as soon as possible, however, to the more open nursery beds as they are becoming overcrowded in their present quarters. The weather, one may reasonably expect to be more suitable for them henceforward. The soil, being on the heavy side, suits these Bunch Primroses and they form fine plants with masses of roots. Amateur cultivators sometimes lose much by retaining their young stock too long in shallow boxes; huge masses of blossom can only be obtained from big, well-established plants.

GIANT DAISIES.—These are more tenacious of life, when grown under adverse conditions, than are the

Polyanthus. Those who garden upon sandy soils must not, however, expect to grow as fine plants and flowers as those who have a more retentive loam. From sandy soils in various districts I have, during the past few years, seen many poor specimens. The sand, through the action of earthworms, strong winds, hoeing and other causes, is apt to lodge in the centre of each young plant, which is much checked in consequence. An occasional watering through a rosed watering-can will wash out much sand and greatly benefit the plants.

WALLFLOWERS.—The Wallflower is soon damaged if overcrowded, and, as the seeds are generally sown too thickly and germination is usually good, the plants at once rob each other. The main root of a Wallflower is, distinctly, a direct continuation of the main stem and so it can penetrate easily between bricks and stones and find sustenance. When treated as a spring bedder, however, it is required to afford a fine display of blossom. Timely transplanting in rather firm, moderately rich ground and at a distance apart, each way, of 8 ins., will ensure handsome specimens for planting permanently in October. If however, the plants are to remain in their nursery quarters till spring they should be planted at least 6 ins. apart. Good strains of the dark and yellow varieties are always pleasing, but there is one, a yellow, named Cranford Beauty, that appeared to me to be of extra high merit, both as regards flower and sturdiness of habit, when I saw it for the first time last spring.

VIOLAS.—For massing, and where strict conformity to shades of colour and form is not absolutely required, seedlings yield a good return for a small outlay. Last spring I saw three batches of plants of very high merit in mauve, lavender and light and dark purple colours and all were very effective. Nicer tufts are secured if at the present time all plants are afforded ample room in a quite open quarter and all flower buds are promptly removed as they appear.

The same careful attention should be given to the double and single Arabis, Campanulas, Primulas for the rock garden and Sweet Williams. The latter, neglected, become weeds; properly cared for this plant is one of our most attractive border flowers. The strains have been immensely improved of late.

GEO. GARNER.

CORRESPONDENCE

IRIS PRICES.

MR. GIBSON'S recent article (page 355) leads me to protest against the prices at which many of the older varieties are being sold. In a catalogue I have just been sent, one is told that Irises increase rapidly, and that it is as easy to grow a good Iris as an inferior one. True! Yet there are some forty varieties listed which have been in commerce ten years or more, whose prices range from 2s. 6d. to £1 1s., e.g., Standard Bearer (1904), 2s. 6d.; Mercedes (1905), 5s.; Col. Candelot (1907), 10s. 6d.; Mme. Durand (1912), £1 1s.; Crusader (1913), 10s. 6d.; Souv. de Mme. Gaudichau (1914), 15s. In some cases prices have actually been raised since last season. The prices, too, of recent French varieties, such as Ambassadeur, Medrano, etc., are also out of all proportion to the prices at which they were distributed by their raisers. When literally scores of new varieties (all, of course, quite distinct, and a great advance on old varieties!) are being put on the market at prices ranging up to £10 10s., older varieties might well be reduced to something within the reach of the ordinary citizen.—B. R. LONG.

VIOLA FLOWERS AND THE LEAF-CUTTING BEE.

IS it not unusual, at least in this country, for the leaf-cutting bees to make use of any other material than the leaves of Rose bushes in making their nests? In my garden during the past fortnight, however, one of them has been cutting Viola petals. Only the white or pale yellow Violas have been cut, the mauve and purple ones being untouched. I enclose some specimens for your inspection.—(Mrs.) M. RANDOLL.

[The flowers sent shewed the removal of the circular and oval patches characteristic of this insect.—ED.]

A HANDSOME HYDRANGEA.

HYDRANGEA hortensis Mariessii, which is now-a-days surprisingly little seen in gardens, differs from the general run of hortensis varieties in that the marginal flowers only are sterile, thus giving the large trusses somewhat the appearance

of a delicate mauve pink variety of the Guelder Rose, except that the sterile florets and, indeed, the inflorescence as a whole are much larger. A

ALSTROEMERIA AURANTIACA IN A SHRUBBERY.

diameter of 3in. is quite an ordinary dimension for the sterile flowers.—S. N.

THE HERB LILIES.

I WAS pleased to see the note from your correspondent "W. I." (page 404) on the Alstroemerias. For some reason these lovely plants are not grown to anything like the extent they were some years ago and it is well they should be brought to the notice of garden lovers, for they are really worthy of their old-time popularity. As regards A.

aurantiaca, however, a word of caution is necessary for it is a rampant grower in a soil which is to its liking and it will speedily encroach on and crowd out its neighbours, and as it sends its roots down to a great depth, much labour is needed to eradicate it. It is well, also, to cut away the seeds before they ripen if increase in this way is not desired, for on a hot sunny day the ripe capsules burst with great force and the seeds are scattered for several feet round the parent plant. Open spaces in the shrubbery are good positions for it and it will grow and thrive for years in such places. Its beautiful orange-coloured flowers are among the best for cutting, lasting in water much longer than most summer flowers. I enclose a photograph taken recently of a large group in a shrubbery which was quite old when I took charge thirteen years ago.—H. C. WOOD.

THE SHOWY MEADOW SAFFRON.

I AM anxious that those who wish to possess some of the best of the autumn-flowering Meadow Saffrons, or Colchicums, should secure them as early as possible if they are to have the full pleasure they can yield this autumn. This can only be secured by procuring the corms very early and planting them at once at a depth of 3ins. to 4ins. in ordinary soil, 6ins. in light earth and 2ins. in very stiff clay. Some bulb dealers offer for delivery in the end of August and early September, and if this can be arranged it is about the best time for planting. This may be delayed until later, but it is always advisable to plant in August if possible.

Of all the Meadow Saffrons none is more beautiful than *C. speciosum*, which has been likened to a Tulip, so large are its handsome blooms, which open out well to the autumn sun, and in a group make a lovely feature of the garden. The flowers of the typical *C. speciosum* are a fine purple with a white centre and a stout ivory-white tube. Spearling through grass or some dwarf carpeter these big flowers look very ornamental. There are several varieties. A good one is *C. speciosum maior*, with larger flowers. Still finer is the variety *C. s. rubrum*, which has the tube red or purple as well as most of the segments. There is also a very handsome ruby-coloured variety with deep

THE REALLY HANDSOME HYDRANGEA HORTENSIS MARIESSII.

coloured tube. It goes under various names and is not too easy to get hold of. A true gem is *C. s. album*, the lovely ivory-white one, sent out originally at the price of 45 per corm by a leading firm, but now available for 2s. or little more. It ought to be in every garden. — SCOTIA

BOISSIER'S GLORY OF THE SNOW.

CHIONODOXA LUCILLE has long been known as one of the most charming of the Glories of the Snow, and ever since its introduction it has been recognised as one of the most charming of our spring flowers. It is not generally known, however, that the form in general cultivation is not the same as the one originally found by Boissier and described by him in glowing language. The *Chionodoxa* named *Lucille*, which was first introduced, flowers a little earlier and is not such a fine blue as Boissier's plant. Within recent years the latter has come into

commerce and is one of the most delightful of all. It resembles the other in the possession of a large white centre, but the blue which surrounds this is much deeper, yet of great brightness. Tastes will not agree in everything and there may be some dissent from my view that Boissier's variety is superior to what is known as the type. It is distinct, also, from *C. Lucille* Timoli or Timolusii. All these three may be cultivated with advantage, either in clumps or masses in the rock garden or grass or in the front of the border. Bulbs are not expensive and may be obtained from most bulb dealers and planted at a depth of 2 ins. to 3 ins. as soon as obtained. Boissier's Glory of the Snow also makes a good pot plant, putting the bulbs almost close together and bringing on slowly in a cool house, or, better still, plunging the pots outside and bringing them in as soon as the plants show flower. — S. ARSOTT.

THE DIAMOND - BACK MOTH

THIS moth, known by entomologists as *Plutella maculipennis* (Curt.), which now and then becomes very destructive to crops of Turnips, Cabbage and Swede, is a more or less common pest of gardens; and its presence in some numbers on Turnip, Swede, Brassica seedlings and Mustard in Lincolnshire, and the fact that it has been reported from several other counties, is sufficient justification for a survey of its life history and the methods of control.

In 1851 the caterpillar of this moth is recorded by Ormerod ("Manual of Injurious Insects") as appearing in "enormous numbers both in England and Ireland, in some instances almost clearing away the attacked crop." It is further stated as being very widely distributed over Europe and occurring even in South Africa. The pest usually occurs in epidemic form, in some years committing serious devastation and in other years doing so little damage that its presence is scarcely noticeable. Thus in 1891, according to Theobald ("Textbook of Agricultural Zoology"), "The east coast of Great Britain was ravaged by countless numbers of this moth, whose larvæ fed on Turnips, Cabbage and most other cruciferous plants, devouring the leaves down to the midrib." The same authority goes on to say that it was estimated that this little pest, which is well known over most parts of England, caused twenty thousand pounds' worth of damage to root crops alone.

The small yellowish eggs are laid on the backs of the leaves of cruciferous plants and when the minute caterpillars are hatched they eat round holes, resembling shot holes, through the leaves, or else tunnel for a time in the interior of the leaf. As they grow they feed quite openly on the backs of leaves, eating out irregular holes in the tissue, sometimes leaving the upper epidermis intact. The shot holes are usually the first sign of the presence of the pest. When disturbed the caterpillars throw themselves off the plants on which they are feeding and hang by a fine silken thread (Fig. 1); by means of this, when danger is past, they regain their position on the leaves. The larvæ are greyish in colour at first, but as they grow and shed their outer skins they assume a pale green tint which harmonises very well with the leaves on which they are to be found. This harmony is particularly noticeable when the larvæ are feeding in Mustard flowers; they spin the flowers loosely together, and lying along one of the threads towards the inside of the flower head may be easily mistaken for one of the small green stalks of the flowerets. Though as individuals the larvæ do little damage, being only about half an inch long

when full grown, when they appear in large numbers, as many as sixty to seventy to a young Cauliflower plant, they become a serious pest. Miss Ormerod states that as many as 240 have been counted on a single plant of moderate size, and it may be imagined that a pest in such numbers, feeding for four or five weeks, will do considerable damage. In 1921 the Ministry of Agriculture (Report of Insect Pests) records an attack in Anglesey,

CATERPILLAR OF DIAMOND-BACK MOTH.
(Much enlarged.)

where, in one case, it was calculated that there were 182,700 larvæ per acre.

In Lincolnshire the attack has been developing since about the middle of July, and in several gardens which the writer has inspected there is

hardly a cruciferous plant, from Radishes to autumn Cauliflowers, free from the pest. In this district, where large acreages of Brassicæ are grown for market, the attack may become serious, but

THE ADULT INSECT (ALSO ENLARGED).

weather conditions and natural enemies may yet effectively check its development. Constant heavy rains appear to be detrimental to the growth and maturing of the caterpillars, which are also particularly prone to the attacks of insect parasites such as ichneumonids and braconids.

When fully fed, the greenish larvæ, which are, characteristically, spindle shaped and have yellow or brownish heads, spin themselves delicate, silken-netted, whitish cocoons on the backs of the leaves, on dead leaves or on the ground. These cocoons are really silken tubes in which the insects pupate, leaving their cast skins outside, adhering to one end of the network. The pupæ are at first pale yellow, but gradually become darker and mottled as development goes on. The pupal stage lasts for two to three weeks, at the end of which time the insects work their way out of the silken tubes, the pupal coats split, and the perfect insects emerge.

The following is Theobald's description of the adult (Fig. 2): "The moth has long narrow wings, the fore-pair being reddish—or slaty-brown, with a pale yellowish white border posteriorly; the hind wings are gray with long fringes of hair, a feature seen in all *Tineidæ*. When the wings are folded the pale edges of the front ones come close together and form diamond-shaped areas, hence its popular name."

It will be realised that owing to the feeding habits of this pest it is rather difficult to cope with, but it can be satisfactorily controlled in gardens by spraying with lead arsenate so as to wet the under surfaces of the leaves. This can be done by using a syringe with an elbowed nozzle which directs the spray to the under sides of the leaves with the least amount of difficulty. The spray should be made up in the following proportions: Soft water, 6 gallons; lead arsenate paste, 1 lb.; soft soap, 1 lb.

Another method of treatment is to brush the plants lightly with a bundle of twigs, which causes the larvæ to throw themselves off the plants; the twigs are then drawn between the rows so as to break the silken cords and thus leave the caterpillars exposed on the surface of the soil, where they can be sprayed with paraffin emulsion made up of soft soap, 1 lb.; paraffin, 1 pint; soft water 4 gallons.

This spray is prepared as follows: Dissolve the soap in 1 gallon of the water, add the paraffin and syringe vigorously to get a good emulsion. Now add the remainder of the water, agitating the mixture briskly while doing so. It is most important to secure thorough emulsification before applying the mixture.

There are two broods of larvæ per annum, the second brood remaining as chrysalids among dead leaves, rubbish, etc. Refuse which is likely to harbour these insects should be destroyed by

burning; and, since the larvæ feed on them, cruciferous weeds should always be kept down so as to prevent the possibility of an attack originating with them. HERBERT W. MILLS.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Mushrooms.—Where horse droppings are available they should be collected and placed in a dry, open shed until the quantity is sufficient to make a bed. They should be turned frequently until all the rank steam has escaped, then the material made quite firm and the spawn inserted an inch deep at a temperature of 80°. A covering of finely sifted loam should be given, and a layer of straw will tend to keep the bed moist. Syringe the house occasionally and, if the bed becomes dry, a light sprinkling of tepid rain water will be beneficial.

Celery.—Continue to earth up Celery, choosing fine weather, when the foliage is dry, for the operation. Remove all weeds and decaying leaves and after the soil has been finely broken up work it among the plants with the hand, and prevent any falling in the centres.

Dwarf Beans.—If brick pits are available a sowing of Dwarf Beans may be made to furnish a supply during late autumn. The soil should be enriched with manure and well dug over with a spade. Before sowing, make the soil fairly firm and, if needed, moist, then no water will be necessary until germination has taken place. Syringe the foliage daily if the weather is hot. The lights will not be required until there is danger of frosts.

Beetroots.—The roots from an early sowing should be lifted before they become too large, and then stored in ashes in a cool shed. The tops should be broken or cut off, not too near the crown or bleeding will follow and the roots thereby be robbed of their goodness.

The Flower Garden.

Propagation.—Quantities of Pelargoniums should be propagated, for filling the beds next summer, and for that popular bedding Pelargonium Paul Crampel there is nothing better than 3 in. pots in which to place the cuttings. The receptacles should be well drained and filled with sandy soil, five or six cuttings being placed around the edge of each pot. Arrange them on a shelf in a greenhouse and keep the soil just moist, but not really wet, or many will damp off. Other cuttings that should be inserted are Verbenas, Calceolarias, Coleus, Margerites and other Pelargoniums. All will readily form roots at this period of the year.

Border Carnations.—When the layers are rooted they should be severed from the parent plant and after a few days removed to their flowering quarters. Sand and old mortar rubble may be added to the soil if it is of a heavy nature. Some growers pot them off and winter them in cold frames, but in this case the plants should receive plenty of air and be grown as hard as possible or many will suffer from damp.

Spartium junceum.—Throughout July this bright yellow shrub has been most effective in the wild garden, where it is represented by several bold groups. It is readily raised from seeds, which can either be sown directly they are ripe or early in the spring. They will germinate in a cold frame, and, when the seedlings are large enough, they should be potted off singly and grown on in pots until they are set out where they are intended to bloom. This plant does not appreciate removal from the open ground.

The Hardy Fruit Garden.

Early Pears.—Early varieties, such as Williams' Bon Chretien and Jargonelle, will not keep for any length of time, but with a little forethought the season can be prolonged. Pick a few of the ripest fruits each day, and if they are not ripening fast enough place a few in a warm room. They should be consumed directly they are fit.

Wall Trees.—Although early in the season aphids was very troublesome, where the trees were duly sprayed they are now tolerably clean and making plenty of growth. Shoots needed for extension or replacing old wood should be tied to the wires, and any surplus growths removed, while all excessively strong ones should be pinched or entirely cut out. Ripening fruit will need protection from birds, ordinary fish netting being best for this purpose. Where wasps are troublesome a bunt should be made for their nests, and wide-mouthed bottles

containing some sweet substance, such as beer, should be hung at intervals on the branches of the trees. Gather the fruit when ready, and if the weather is showery the trees will require frequent overhauling.

Fruits Under Glass.

Peaches.—The late crop of Peaches and Nectarines growing in houses where little or no heat has been employed, are approaching the ripening stage, and the syringing of the trees ought to be discontinued directly the fruits begin to ripen. Plenty of air should be admitted both from the front and top ventilators and a few inches left on throughout the night. A free admittance of air will cause the fruits to be a better colour and, moreover, the flavour will be improved. Tie in any growths that may be necessary and see that the fruits are exposed to the light, by pulling on one side any leaves that may be obstructing the rays of the sun. The roots should be kept moist and directly the fruit has been gathered, syringe the trees with an approved insecticide and to ripen the growth admit all the air possible.

Tomatoes.—The plants are producing good crops, and owing to the use of the white fly fumigant as advertised in THE GARDEN this pest has been kept well under control. Continue to remove side growths and plants that have several trusses of fruit set may have their tops also cut out. Feed the roots with liquid manure, or Thomson's manure, and see that the plants are well supplied with water.

T. W. BRISCOE.
(Gardener to W. R. Lysaght, Esq.)
Castleford, Chapstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Celery.—A commencement may now be made with the earthing up of this important crop. Remove all side growths and tie the plants close, but not too firmly, with a piece of raffia. Those having access to river or sea sand will be well advised to blanch with pure sand. In order to do this, lining boards should be placed on edge on either side of the plants and a little soil pushed against them from the edge of the trench, after which the sand should be placed around the plants between the boards up to the desired height and the portions of the trench behind the boards should then be filled up with soil to the same height. The boards should then be pulled up and the process repeated until the whole crop has been treated. If sand is not available, the soil should be broken up finely before surrounding the plants with it. The earthing up should be done by degrees as the plants develop. If the ground is dry the crop should be liberally watered before commencing to earth up.

Spinach.—A good breadth of Spinach should now be sown on a south border, to stand the winter and to furnish a supply in spring. Some authorities advise to sow the prickly or winter Spinach, but during many years of experience I have found the round or summer Spinach, which is of superior quality, quite hardy. Allow 15 ins. between the rows.

General Work.—Promptly clear away the remains of all harvested crops and hoe and rake the vacant quarters. Keep the Dutch hoe going among all growing crops, thin late sown Turnips and Lettuces. Water growing crops should drought occur, stirring the soil afterwards with the hoe.

Fruits Under Glass.

Late Vines will now be ripening off their fruits, and a rather dry, buoyant atmosphere should be maintained. Any cracked or deformed berries should be removed with the scissors, also any that may have been tampered with by wasps. Means should be taken to cope with these pests. Bottles containing a little ale and sugar, if suspended from the trellis, prove very good traps. Jars containing a little half-putrid fruit are also very serviceable traps; reference is, of course, made to glass jars with narrow mouths.

Orchard House.—Remove the various trees to the open as the fruits are harvested. Thoroughly

cleanse the trees by the vigorous use of the garden engine or the syringe and, if pests are present, employ a suitable insecticide in the water. Stand the trees in full sunshine and either plunge the pots, placing a small inverted flower pot at the bottom of each pot, or stand the pots on boards or on a layer of coal ashes. Traps should be employed here, too, to cope with the attacks of wasps, which are sure to occur.

Melons.—Mid-season crops will now be ripening off their fruits and rather dry conditions both of soil and atmosphere should obtain. Late crops should be kept growing by the maintenance of a brisk temperature and by a plentiful supply of moisture in both soil and atmosphere. It fruits are not yet set, watch for three or four female flowers developing simultaneously or within two days of each other, and promptly impregnate them with the pollen from a male flower, either transmitted by direct contact with a picked flower, or by means of a camel hair brush. This operation should be performed at midday or rather before it.

Strawberries.—See that the potted plants are kept regularly supplied with water and should any of them attempt to develop runners, remove the latter promptly.

The Flower Garden.

Pelargoniums.—These showy flowers are not so much employed in the flower garden as they used to be, but still have their admirers, and this applies more especially to the Ivy-leaved section. The work of propagation should now be taken in hand, commencing with the Zonals of which Paul Crampel is the favourite. Ordinary well drained propagating boxes are the most convenient receptacles for the cuttings. Equal parts of loam, leaf-mould and clean sand form a suitable rooting medium, but the leaf-mould is not essential. Pack the soil very firm in the boxes, leaving sufficient space for watering. Choose, as far as possible, short-jointed, well ripened shoots, and these will be found where they have enjoyed most air and light. Having trimmed and "made" the cuttings, insert them with the aid of a smooth, hardwood propagating pin of sufficient thickness to admit of the cutting being inserted without being bruised. Water the boxes well through a rose and stand them on some hard bottom where they will have the benefit of full sunshine; no further watering is, as a rule, required until after the cuttings are rooted.

Chrysanthemums.—Most of these will now be in the bud and will be benefited by an occasional light application of sulphate of ammonia or superphosphate, always running over the ground with the Dutch hoe immediately after the application. Keep a look-out for greenfly or the leaf miner; the former should be held in check by the use of nicotine in some form and the latter by a solution of quassia chips.

Climbers.—Young, partially developed plants should be trained, nailed or tied, as they extend, and any that have recently flowered should have the spent blooms removed. Loose, straggling growths on Ampelopsis Veitchii should be cut away, as when blown about by the September gales they are apt to tear away portions that are clinging to the wall. See that recently planted specimens do not suffer for lack of water.

CHAS. COMFORT.
(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian.)

GREENHOUSE AND CONSERVATORY.

Achimenes.—As the earlier batches pass out of flower, they may be stood in cold frames, gradually withholding water as the foliage and stems die off. This latter process, however, should not be hurried by withholding water too soon. When they have died down, they may be stored dry in their pots for the winter; or they may, to save room, be turned out and stored in pots or boxes with dry sand. Later-flowering batches should be kept going by feeding them with diluted liquid manure or guano. These plants are very subject to attacks by white fly, which should be kept in check by fumigating with sodium cyanide or some other approved remedy.

Gloxinias as they pass out of flower should be treated in the same way as the above as regards watering and storing for the winter.

Isoloma hirsutum is a very useful plant for the greenhouse, as by raising successional batches it may be had in flower more or less all the year round. It is easily propagated at any time by means of the young shoots which spring from the base of the old plants; they root readily in a close case with slight bottom heat. President Chandon is a fine variety which may be treated in the same way.

Chrysanthemums should now be assisted by frequent applications of diluted liquid manure, varied with other approved fertilisers. The rule when applying manures is little and often, as strong doses may injure the roots; manures should never be applied when the plants are dry at the root. If they are dry they should first be watered with clear water. The plants should be neatly staked and regularly tied to prevent damage during stormy weather. A sharp look out should be kept for aphids, which may be destroyed by dusting with tobacco powder. Earwigs often prove troublesome, especially when the plants are stood near hedges or bushes; they should be regularly trapped and destroyed, as they do an immense amount of damage to the young buds. Small pots stuffed with dry hay, or pieces of broad bean stalks make excellent traps for them. During hot, dry weather the plants should be kept well syringed morning and evening.

Richardia africana.—Plants that have been rested in pots should now be shaken out and re-potted, giving them a very rich compost, as they are gross feeders. Stock that has been planted out should be lifted early next month and placed in suitable sized pots; where large specimens are required, three or four strong plants may be placed in 10 in. or 12 in. pots. They should be stood in cold frames and carefully watered until they have made a quantity of roots. When they are in full growth they enjoy ample supplies of water and frequent applications of diluted liquid manure and soot water.

Solanum capsicastrum.—Plants that have set their fruit may now have the tips of the shoots pinched out, as this helps the fruits to develop. If grown in pots they require ample supplies of water, as they are free-rooting plants. They should be kept well syringed as they are somewhat subject to attacks by red spider. Where the plants have been planted out for the summer, they should be lifted towards the end of the month and placed in suitable sized pots. Several days before it is intended to lift them they should be cut round with a spade or knife, at the same time soaking them thoroughly at the root. The same advice applies to other plants, such as *Bouvardia* and *Salvia*, that have been planted out for the summer.

Propagation.—The propagation of many plants that are required for next year should be undertaken at this time. The list includes quite a number of *Begonias*, such as *B. acuminata*, *Corbelle de Feu*, *Ingrami*, *fuchsoides*, *coccinea*, *l'Esident Carnot* and *Luzerna*. The last three are large, strong-growing plants that are useful for planting out to furnish pillars and rafters in the greenhouse.

Coleus.—Cuttings to provide a stock of plants to carry over the winter should now be put in. This also applies to quite a number of soft-wooded plants, as young plants are more likely to winter safely than old ones.

Calceolarias.—The sub-shrubby species and varieties should be propagated at this time. They include such species and varieties as *C. integrifolia*, *Clibrari* and *Allardii*. Some of the *C. alba* hybrids, such as *Veitchii*, are very useful for conservatory decoration. Cuttings at this time are often hard and somewhat difficult to root and better plants are generally obtained by re-rooting stock from the first sets of rooted cuttings, as plants from the young soft shoots make freer growing plants.

Royal Botanic Gardens, Kew. J. COULTS.

BOOKS

Gardening for the Novice.—There is quite a host of books written specially for the novice and for those who have progressed a very little way along the path of horticultural knowledge. We picked up Mr. Thomas's book* with pleasurable anticipations and though it turned out to be a more elementary treatise than, from its title, we had expected, we were in no way disappointed. Some of the statements made seem a little controversial—to put it mildly. As, for instance, "There are two schools of garden planning" (the formal and informal), "and everyone must decide to which of them he belongs. He certainly belongs to one of them." For our own part we believe that most work-a-day gardeners and the very cream of present-day landscape gardeners, belong to neither. They use the best features of both.

Again, Mr. Thomas writes, "If the matter is not clear, let him consider whether the path from the gate to the house shall be straight or winding." How long a path? and what sort of a house? At this rate we shall be having Mr. William Robinson written down as a "formalist"!

The first chapter gives general but on the whole helpful (*mildly* what we have written) hints about planning the garden. Succeeding chapters cover "Why Amateurs Fail," "The Right Time," "Pruning Problems," "Garden Paths"—very sound this—"Plants that Remain Gay a Long Time," "Plants that are Best Left Alone," "The New Shrubbery," "The Lawn," "The Hardy Flower Border," "The Rock Gardening," "The Alpine Border," "The Water Garden," "Propagating Trees, Plants and Shrubs," "Rose Growing," "New Flowers and Shrubs," "Hardy Lilies," "Gladiosi," "Sweet Peas," "Hardy and Half-Hardy Annuals," "Climbing Plants," "Carnations" and "Hardy Bulbs."

There are a number of minor points which, in our judgment, might be criticised—every book, of course, is open to criticism—but we shall content ourselves with mentioning one or two which, perhaps, Mr. Thomas will reconsider for the next edition. Why are the *Aquilegias* included under "Plants that Remain Gay a Long Time"? We should have thought that both the *Lupin* and the *Delphinium* had far greater claims, though both are omitted. Again, strictly speaking, *Agrostemma coronaria* is not a hardy biennial. Under "Plants Best Left Alone," are included *Erica* and *Gentiana acaulis*. Now, if planted deeply, all dwarf *Ericas* propagate very easily at almost any season by division, and the *Gentiana* never does its best if left too long (say above four years) in one place. It tolerates division as freely as anything we know. A very excellent chapter on lawns is, in our opinion, blemished by recommending top-dressing with stable manure. We thought the idea was quite out-dated.

Care has been taken to introduce no undue complexity, but in some cases, accuracy has been needlessly sacrificed to attain this end, as when *Trilliums* are broadly described as white, which is certainly true of the one recommended, *T. grandiflorum*. Despite such minor blemishes this is a valuable book and not its least useful part is the series of tables which occupy some eighty pages. "Flowers for Every month," "Pruning Hardy Shrubs and Plants," "Plants for Shady Borders," "Selections of Roses" for various purposes, "Selections of Plants to Colour," "Trees and Shrubs Tinted in Autumn," "Berried Trees and Shrubs," "Evergreen Shrubs," "Deciduous Flowering Shrubs," "Greenhouse Flowers," "Manures," "Pests," and "Plant Diseases." Chapters on "Indoor Gardening," "Fruit Gardening" and "Vegetables," round off an exceedingly useful volume.

Variety.—Mrs. Francis King's writing is now fairly familiar to British gardening enthusiasts. She writes pleasantly and, unlike certain American novelists, in English. The ideas in the present book are, naturally, not all applicable to gardens in Great Britain, largely because our climate is suitable for a much wider selection of plants than can be induced to succeed in the Eastern States of the great English-speaking Republic. Mrs. King has not hesitated, either, to borrow ideas from other writers, though she does not, like some writers on gardening topics, dress them up in her own language and pass them off as original. We have one bone to pick with the lady, however. We do think that

* "Cassell's Guide to Gardening," by H. H. Thomas, 276 pp., 8vo. Published by Cassell and Co., Limited, La Belle Sauvage, E.C.4. Price 8s. 6d. net.

† "Variety in the Little Garden," by Mrs. Francis King, 120 pp., 8vo. Published by the Atlantic Monthly Press, Boston, U.S.A. Price not stated.

when she borrows fairly extensive passages from English periodicals, it would be an act of courtesy to own the exact source. If "Variety in the Little Garden" came to be analysed a surprising proportion would be found to be extracts from various sources, used, it is true, with the utmost effect, but still lifted bodily from periodicals—*THE GARDEN*, among others—without acknowledgment.

Another patent defect in this book is a reprehensible carelessness with regard to botanical names. We might have thought that they had different rules in U.S.A. for the "cases" used for specific names to those in use "on this side," were it not that the same species are variously referred to on succeeding pages. Misspellings, too, are more common than they should be.

These things are matters of fact. When one comes to matters of opinion, one is on less certain ground, yet a preference expressed in one place for crazy paving rather surprised us, we must confess. Again, Mrs. King's objection to the Birch (page 104), is more than a little surprising. She cannot, we think, have seen Surrey woodland with its Birch and Bracken or better still, Birch and Scots Pine. The two last, in particular, associate so admirably. Then, too, a clump of Birches may be used with effect in even the smallest garden. However, the care with which we have marked what, with due respect we consider blemishes, only proves the general worth of a book which, we are sure, many English garden-lovers will wish to have on their bookshelves.

R.H.S. Plant Trials.—The Royal Horticultural Society desires to compare the merits of wild species of Tulip as garden plants and would be grateful if those having bulbs of such available would send examples (say six) of each to The Director, R.H.S. Gardens, Wisley, Ripley, Surrey (Horsley Station, Southern Railway), so as to reach him by the middle of October, 1923.

In addition, the Society, bearing in mind the difficulty of exhibiting Rock Roses (*Helianthemums* and *Cistuses*) and the number of promising new seedlings that have been recently raised, will carry out a trial of these plants at Wisley during the coming year. Three plants of each variety for trial should be sent so as to reach the Director, from whom the necessary entry forms may be obtained, by the end of October, 1923.

Answers to Correspondents

FLOWER GARDEN.

CHRYSANTHEMUMS ATTACKED (B. S.).—The foliage has been attacked by the minute maggots of a small, two-winged fly and the best method of dealing with this is to spray the plants with a nicotine wash. Dusting with soot would help to keep the fly at bay. All spraying should be done after the bright sun is past.

THE GREENHOUSE.

SCHIZANTHUS UNSATISFACTORY (Disappointed).—Our correspondent must make sure of possessing a good strain of seeds of the *Wisetonensis* or hybrid selections. Seeds should not be sown before the end of August at the earliest, about the middle of September would be better. Good loam and leaf-soil in equal proportions are suitable for sowing the seeds in and for the first potting. Make use of a pan, well drain and firm the soil in it, apply water and one hour later sow the seeds thinly, covering lightly. A cool greenhouse will answer at this stage. Pot singly in small pots, the resultant seedlings, when quite small, water carefully and still retain the plants in an airy position. In October shift the plants to 5 in. pots and winter on a high, sunny shelf. In February give the plants a final repotting, using a more lumpy compost. Premature flowering may be caused by too early sowing or by allowing the young plants to become potbound. Plants from a good strain do not require stopping to ensure a well balanced specimen.

KITCHEN GARDEN.

POTATOES ATTACKED (A. B. C.).—The Potatoes are badly attacked with corky scab, due to *Spongospora subterranea*. The worst should be burnt and the others cooked. On no account plant them or let the peelings, etc., get into the ground unburnt. The trouble is quite distinct from wart disease.

FRAGRANT ROSES.

*It is a reproach, often
justly levelled, that the
Modern Rose has form
and colour but no scent.
It is certain, to get the
real "attar" perfume,
one must go back to the
old varieties. Many of
these will be found in
our Illustrated Rose
Catalogue, which we
shall be pleased to send
to readers of this paper.*

[AUGUST 25, 1923.]

THE GENUS VIOLA

A PART from the numerous garden varieties, the *Viola* family is a very large one, consisting of about 200 species, the greater number being spread over the northern temperate regions, while thirty are found in South America, two in South Africa, and eight in Australia and New Zealand. The majority are beautiful woodland plants, and they are also found in hedge banks, open pastures and in cultivated fields. Most of the species are perennial and the plants are of dwarf habit.

In this country they are nearly all easy to grow in light, rich soil, preferably in half shady situations, but a number of them flourish in the open border. In many of the species the flowers are cleistogamous, the larger petalled flowers appearing first, but producing little or no seed, while later, small-petalled, fertile flowers are produced which furnish seed. The section to which the Wild Pansy (*V. tricolor*) belongs is an exception, for in this case all the flowers are fertile. *Violas* can be propagated by division of the roots in the autumn or spring, by seeds, runners or cuttings. Somewhere about fifty species are in cultivation, chiefly in the gardens of a few enthusiasts, and in Botanic Gardens. The following are some of the more attractive and easily grown kinds which are well worthy of culture.

V. ALPINA.—This species comes from the Eastern Alps where it is found at high elevations. It has small, oval-shaped leaves borne on long stalks, while the flowers are purple and have a short spur.

V. ALTAICA.—This species is supposed to be one of the parents of the cultivated Pansy of our gardens, all those with pale yellow petals with an undulated margin being derived from this plant. It is a native of the Altai Mountains and has large, pale yellow flowers, with a few dark purple lines near the base of the petals. It was introduced into cultivation over a hundred years ago and is easily propagated by seeds or cuttings. The seedlings vary in colour.

V. ARENARIA.—This is a rare little native plant, found in Teesdale, but is also found in various parts of the

Continent of Europe. It forms a tuft and has small leaves and pale blue flowers.

V. BIFLORA.—The twin-flowered Violet is a dainty little plant, found on the Alps of Europe, growing in the crevices of rocks and on rocky banks. It has small, bright yellow flowers and should be given a moist, half-shady position. It is an old inhabitant of our gardens, having been grown since 1752.

V. BLANDA.—An early-flowering species from North America, this has pubescent leaves and small white, faintly scented flowers, veined with lilac.

V. CALCARATA.—Well named the "Pansy of the Alps," this attractive species in its various forms is found in alpine pastures, spread over the whole of the European Alps. It is a lovely plant, forming tufts of leafy stems about 3 ins. high, bearing large, violet-purple flowers, each with a long spur. It is found in stony ground among boulders, spreading by means of underground stems, rambling among the stones and flowering freely among the short grass. This charming species is easily grown in half-shady situations, or even in full sun, provided it receives sufficient moisture for the roots. It should be planted in

very gritty soil, with thorough drainage, but it must have plenty of water in the growing season. It is easy to propagate by means of cuttings in summer, or by division after flowering, as well as by seeds. The colours of the flowers vary from violet-purple to pale lilac and pure white. There is also a lovely clear yellow form known as *V. Zoysi*, which is found in the most Eastern Alps of Carinthia.

V. CANADENSIS.—This is a handsome plant from Canada, growing about 1 ft. high, with sweetly scented, white flowers, tinged with violet. *V. Rydbergi* is the Colorado form of this species. Both plants require a shady situation.

V. CANINA.—The common Dog Violet is a well known native plant with blue flowers, that have a yellow spur. There is also a pure white form.

V. CENISIA.—A lime-loving species from the Alps, with violet flowers, and a slender, arching spur, this grows about 6 ins. high and has slightly hairy leaves.

V. CORNUTA.—The Horned Viola is a free-growing species forming dense carpets of foliage and bearing large, light purple flowers. It is a valuable spring and summer-flowering plant. It varies much in colour, there being a pure white-flowered variety as well as the rich purple form, *purpurea*. It comes from the Pyrenees and is supposed to be one of the parents of the bedding *Violas*. It is a good perennial and easily increased.

V. CUCULLATA.—This Violet has the margins of the leaves turned up so as to resemble a kind of cup. It is a common North American Violet and will grow almost anywhere. The

VIOLA ARENARIA ON MORaine AT BROCKHURST.

flowers of a pale or purple and of good size. The flowers of a pure white variety, *V. septentrionalis*, with striped blue and white flowers, is a form of this species.

V. DECLINATA is a charming little plant from the Eastern Alps and Balkans, with rich rosy-purple flowers, having a yellow eye. *V. bosniaca*, with rosy-pink flowers is a form of this species from Bosnia.

V. FLAVOLA. This is a very distinct species, growing over 1 ft. high, with erect stems and bushy habit. The flowers are pale blue and of good size. It is a native of Europe.

V. GRACILIS is a beautiful, dwarf, free-flowering kind from South-eastern Europe, with large, deep purple flowers that appear in spring and summer. It is a valuable plant for the rock garden or border, easily grown and increased by cuttings or seeds. Although first introduced in 1817, it has only recently become plentiful in gardens. The variety *valderna* (*heterophylla*) is a charming sort from the Tyrol and Greece, with smaller violet-blue flowers, spotted with darker violet and white.

V. HEDERACEA (*Erpetion reniforme*).—This is a charming species of creeping habit, only 2 ins. high, with lilac-blue and white flowers in summer. It is a native of Australia, likes a moist position and is only hardy in very sheltered situations.

V. LUTEA.—This is considered to be a form of tricolor and has large, yellow flowers with purple blotches. It has been used for crossing with the Show Pansy to produce the modern *Violas*. Var. *amena*, with purple flowers, is found on the Welsh mountains.

V. ODORATA (Sweet Violet). The delightful fragrance of this species makes it a favourite in every garden. It is a native of this country and there are numerous varieties, which have been greatly improved for garden purposes. The flowers range in colour from blue to red, purple and white. *V. odorata pallida plena*, the Neapolitan Violet, has sweet scented, double flowers of a pale lavender shade. *V. odorata sulphurea* (*V. Vilmorini*), has dark yellow flowers.

V. PALMATA is a North American species, growing in low ground and woods, with palmately lobed leaves and blue flowers.

V. PEDATA. A beautiful plant, this is found growing in dry sandy woods on rocky hills in North America. The leaves are pedately divided into about seven narrow divisions, while the large, bright blue flowers are freely produced in early summer. *V. p.* var. *bicolor* is a handsome form with the two upper petals of a deep violet colour. There is also a pure white flowered form.

V. PINNATA.—A somewhat rare plant found in alpine pastures on the European Alps, this has palmately divided leaves and violet coloured flowers in June. A form of this species, var. *charophylloides*, has larger and more attractive flowers.

V. PRIMULAFOLIA.—A species from the wet meadows of North America, this has sweet scented white flowers, the lateral petals being bearded.

V. PUBESCENS.—This is a free-growing North American plant, 6 ins. to 12 ins. high, usually found growing in dry woods. It is softly pubescent, with large leaves and yellow flowers, the lower petals being veined with purple lines. The variety *scabruscula* is a form with decumbent stems and smaller, somewhat scabrous leaves.

V. ROSTRATA. This is also a North American species, found in moist, rocky situations. The large flowers are pale blue and have a slender spur.

V. ROTUNDAGENSIS. This is of the same type as *V. cornuta*. It has bright blue flowers, the side petals and lip being striped with black. It flowers from April to August and is a native of France and Belgium.

THE BLUE AND WHITE *VIOLA SEPTENTRIONALIS*, A FORM OF *V. CUCULLATA*.

V. BOSNIACA, RECKONED A FORM OF *V. DECLINATA*, HAS RICH ROSY-MAUVE FLOWERS

THE AUSTRALIAN *V. HEDERACEA* (*ERPETION RENIFORME*).

THE BRIGHT YELLOW *V. BIFLORA* LOVES HALF-SHADE AND MOISTURE.

V. ROTUNDIFOLIA.—At flowering time the leaves of this North American plant are small, but later they develop to a large size, 4ins. in diameter. It is found in shady, rocky situations and bears good sized pale blue flowers.

V. STRIATA.—This is a strong-growing, attractive plant up to 12ins. high. The flowers are cream coloured, the lower divisions being veined with purple. It grows in wet meadows in mountainous districts in North America.

V. SUAVIS.—The Russian Violet is closely allied to our native Sweet Violet, but is distinguished by its pale green leaves and larger, paler flowers. It

was introduced from the Caucasus a century ago.

V. SYLVESTRIS.—The Wood Violet is a well known native plant with bluish-purple and lilac coloured flowers, produced on axillary branches from a radical rosette. It is also known as *V. sylvatica*. There are many forms of this species, including a pure white one.

V. TRICOLOR (Heartsease; Pansy).—A common, very variable annual, found in cultivated fields. The flowers vary from small yellow blooms to large tricolored ones, blue, purple and yellow. It is one of the parents of the garden Pansy. The variety *arvensis* has small yellow flowers. W. I.

NATURALISING BULBOUS PLANTS

THESE are few gardens so small that bulbs may not be naturalised in them. Particularly is this the case if we do not define "naturalise" too strictly. What exactly then do we mean when we state that such and such are suitable for naturalising. Surely most of us mean simply that they may be so planted that, though their presence be, during the resting season, forgotten, they will shew each year and flower profusely and, very possibly, increase by self-sown seedlings. A narrower definition might stipulate that no weeding should be necessary, but to the writer this seems unnecessarily to narrow the field. In the rock garden, weeding is obviously necessary, if only for the sake of appearance and yet some of the most natural and pleasing effects obtainable with bulbous plants may be achieved there.

Of course, to obtain natural effects in the rock garden, the rock garden itself must be tolerably natural—there is no scope for natural planting in the wretched "pocket" rockery which one still finds in some gardens. The rock garden is a particularly happy place in which to naturalise certain small bulbous plants, not only on account of the suitable conditions which can there be afforded them, but because it is a relatively simple task so to arrange them that the beauty of the individual blossoms is brought near to the eye. The various *Erythroniums* and some of the choicer *Fritillarias* come to mind in this connexion, as well as tiny *Narcissi* and *Irises* and choice *Tulip* species.

When naturalising bulbs on rockwork, care must be taken not to make the grouping too formal. Indeed, if this is to be of any size it had better take the form of a drift streaming down from a higher to a lower level and spreading out irregularly. It comes. It is, of course, quite easy to achieve monotony of even the most irregular formation if it is slavishly reduplicated and this must be guarded against. A smaller clump or two, isolated a little from the main body often helps to secure a natural effect. It is not necessary to make the overplanting, which should always be carried out coterminous with the bulb planting. If the two appear to be entirely independent it will serve considerably to enhance the natural effect.

Now for a few species suitable for naturalising on the rock garden. Any of the *Erythroniums* will answer in at least half-shady situations and in a compost consisting largely of decayed vegetable matter. Perhaps the most beautiful of all is *E. californicum* White Beauty. Established clumps often throw spikes 14ins. or 15ins. tall, with blossoms which well repay individual study; moreover it increases fairly rapidly from self-sown seed. Very handsome, too, is *E. grandiflorum*, particularly the form known as Pink Beauty. This is of similar stature to White Beauty and perfectly easy, though it does not seem to increase so rapidly from self-sown seed. Flowers 3½ins. to 4ins.

across are quite usual with this variety. Perhaps even more attractive than Pink Beauty is *E. Johnsoni*, with elegantly mottled foliage. *Nuttallianum* seems to be the freest of the yellow-flowered species. For the rock garden these should suffice.

THE CREAM AND ORANGE ERYTHRONIUM CALIFORNICUM, OF WHICH THE SPLENDID WHITE BEAUTY IS A VARIETY.

but in the woodland wild some of the numerous other species and varieties might have a trial, including the common (and cheap) European Dog's Tooth Violet, *E. Deus-canis*, which is worth growing for its handsomely mottled foliage.

Some of the choicer *Fritillarias* are worthy of a select corner in the rock garden and once happily accommodated may be left undisturbed indefinitely. Such are *FF. pyrenaica* (with purplish flowers), *pudica* (deep yellow), *camtschateensis* (vinous purple), *macrophylla* (tall-flowered pink), and *aurea*, which, however, is at the moment very scarce.

The tiny early-flowering bulbous *Irises* are, perhaps, best on rockwork, if indeed they are to be grown outdoors at all. Those who possess an

alpine house should certainly give it first call upon them. Such are *I. reticulata*, with blossoms of royal purple and gold, almost disproportionately large for its diminutive stature, and the golden *I. Danfordiae*. The early form of *I. reticulata*, known as *Krelagei*, should also be included. These *Irises* need more than ordinary care if their arrangement is to look natural.

Tiny *Narcissi*, which obviously belong to the rock garden are *N. Bulbocodium* and its very distinct varieties (or sub-species), *monophyllum* and *citrinus*. A very gritty soil, with pieces of rock embedded, and consisting for the rest mainly of humus, suits these best. They should, naturally, since they bloom so early in the year, be given situations sheltered from the east, lest some frosty morning the sun scorch them. Very similar conditions suit the quaint *Narcissus cyclamineus* and the Angel's Tears, *N. triandrus*. This last is not very easy, but some of its hybrids are almost as *chic* and distinctly easier to grow, albeit the Angel's Tears and all its progeny are, in our climate, not very long-lived plants. The species

is, as we might expect, therefore, readily replaced from seed. Such other miniatures as *minor*, *nanus* and *minimus* are also best in the rock garden, but the cultivation of these presents no difficulty.

The *Chionodoxas* make lovely patches of clear blue when the rock garden is still hardly awake, but there is no need to confine them to this part of the grounds; they may be massed freely in the wild. All are excellent plants for massing, since self-sown seedlings spring up everywhere, reminding one of a flourishing crop of young Onions. *Chionodoxa Luciliae* is deservedly a favourite, though, contrary to the general impression, there are more forms than one of the plant. The pure white form provides a pleasing contrast with the more typical bright blue ones. *C. sardensis* is deeper in colouring even than the deepest *Luciliae* and *C. gigantea* is a very distinct plant, which carries its larger saucers solitarily and uplifts them to the heavens. The saucers fade at last to seed-pods, the "grass" quietly

withers and allows the overplanting—some rapidly expanding alpine *Columbine*, perhaps—to possess the ground which a little while before was a chunk of heaven come to earth! If we use the phrase bulbous plants in its strict sense, we must rule out the genus *Anemone*. Yet, since we buy the dried tubers of many of these from our bulb merchant, along with our *Tulips* and *Narcissi*, it seems pedantic to except them, the more so as many lend themselves admirably to naturalising. The rhizomes of our Wood *Anemone*, *A. nemorosa*, do not approve of being dried off and choice varieties of the plant are, for this reason, usually offered in pots. It is interesting to make as complete a collection of these forms as possible—but for those who seek the best rather than a

collectible sentiment in Roman made of the indispensable. The semi-transparent, golden-eyed loveliness of the last named in particular is enough to turn the most matter of fact sentimental. Those who collect the leaf-mould for heath garden or the old-fashioned dell from anemone-carpeted wood-land will soon find that they have, indeed, naturalised this beautiful, if common, flower. The choice blue, double and Jack-in-the-Green forms all seem as easy and indestructible as the type in any rather shady corner where their root-run is mainly leaf-mould. We have seen them burgeoning from lateral crevices in a cliff with a north aspect where there was scant room for the rhizomes under

ground. But the soil had been specially prepared for the reception of humus-loving plants such as those indicated, the *Ranunculus* and *Haberleas*.

The chippy tubers of those related species *AA. blanda* and *appennina*, give small indication of the loveliness they afford when in flower. Both these species are so accommodating enough to look lovely in clumps of three or half-a-dozen in the tiny suburban rock garden, and yet to be wholly adapted to massing by the road in the wild. What one loses in the beauty of the individual plant in such a case, one more than makes up by the sea of blue afforded.

(To be continued.)

THE BULB ORDER

IV.—Further Miscellanies.

AS I write I have by my side a bulb catalogue of Messrs. Barr and Sons for 1882. As the gardening world knows, this firm is generally recognised as one which makes a great speciality of bulbs, and which includes in its annual catalogues many comparatively out-of-the-way species and varieties which are not to be found elsewhere, in much the same way that Thompson and Morgan of Ipswich list all manner of uncommon seeds. A comparison between this old list and the same firm's two lists for 1922 is very interesting. We see where great changes have taken place and where there has been nothing much doing but marking time. There are enormous differences in the Daffodil and Tulip sections, but comparatively little in that of the Hyacinths. Freesias have made very great strides, while *Babianas* are much as they were. In the place of five species or varieties of *Nerines* there are no fewer than two and a quarter pages of this Prince of the Autumn to pick from. The early race of bulbous Irises, known as Dutch because it was originally made in Holland (although I fancy Mr. Herbert Chapman's strain has been evolved upon somewhat similar lines) has lengthened the season (to be a bit Irish) of the "small bulbous Iris of Spain" very considerably, while the ancient *Ranunculuses* have done little but look on. I am starting with these. Some time ago I asked if anyone could tell how to grow them, as in times past I had often failed. I was advised to try them in pots. I did, and I also put some in large pans. Both attempts were dismal failures. The bulk was planted on April 4 in a well drained cold frame in fairly light soil. They were left quite unprotected, and the only special care they had was an evening soaking when there had been no rain during the day. At the end of June and during the first three weeks of July there was quite a fair display of bloom which came in handy for cutting. I must own there was nothing of the "twenty blooms on a single root" which one catalogue tells me is quite possible, but all the same I intend to try again. This is why I am suggesting the spending of a few shillings on some of each of the sections—Turban, Persian and French, to put them in the order in which they bloomed here. The Turban nomenclature seems fairly constant, but in the other sections it is nearly all what I call "fancy" naming. In the French, Oracle (pale yellow), Horace Vernet (white) and Orion (deep maroon); in the Persian, Harold (a lovely rose), Fireball (scarlet) and Commodore Napier (yellow); and in the Turban, Seraphique (yellow), Merveilleuse (orange), Groot-vorst (rose), Rosalie (soft rose) and Hercules (white) were the ones I marked. The freest

flowerers were the French. These appealed to me very much, especially as the individual blooms were of a nice convenient size for small vases.

MR. CHAPMAN'S "ROTHERSIDE" EARLY-FLOWERING BULBOUS IRISES.

How far Irises are practical politics for out of doors in our southern counties I do not know. They are, in my own experience is anything to go by, altogether out of the question for Midland and Northern gardens except under glass. When grown under such conditions, with practically no heat, they are a treat when seen in a mass on a sunny day in mid-May or early June. They then open their great big eyes and, eagle-like to prove their worth, look Phoebus Apollo steadfastly in the face:

"Nay, if thou be that princely eagle's bird,
Show thy descent by gazing 'gainst the Sun."
(Shakespeare—"King Henry VI.")

I fear I know nothing of the original species from whence we get our garden hybrids. Many of the best varieties have been raised in Guernsey. Through the kindness of Mr. William Manger I was set up last autumn with a collection of some

of these—Ella, William the Conqueror, Hubert, Vulcan, Evelina, Beauty of Norfolk, among others. When we see a good collection we get all sorts of colours—deep yellow and soft straw, deep crimson, pure white, scarlet, green, palest Cambridge blue, rose and pink—nearly all with lovely dark eyes like Ella, Hubert, Evelina and Emperor of China, one or two striped like Vulcan. As the names of Irises are, comparatively speaking, common to all catalogues, I may mention a few of my favourites: Englishton (a lovely old rose shade), Ella (white, crimson centre), Emperor of China (rich yellow with deep crimson centre), Vulcan (deep orange and red with dark centre), Hogarth (primrose with purple centre), bucephalus major (bright rose), viridiflora (pale sea green with black eye), Hubert or Humbert (dull rose with black eye) and William the Conqueror (cream with maroon eye). A greenhouse of Irises on a sunny day in May with their "soft eyes" which "look love to eyes which speak again" at least equals the scene at the historic Waterloo Ball when "all went merry as a marriage bell." Irises are the very thing for cool glasshouses. Try them and save your own bulbs.

Outside, inside, now outside again! I must say a word for the big three in the bulbous Iris world. In garden seniority the English comes first, then the Spanish and last of all, as one born out of due time—three centuries afterwards—the Dutch. They flower, however, in the inverse order. About the end of May the Dutch set the ball rolling, and as they leave off the Spanish "carry on"; then comes a two or three weeks' interregnum and the English end the sequence. The following are all well worth a trial: In Dutch, Voerman (the white), Van Everdingen (yellow), Apol (lavender) and Poggenbeek (blue). In Spanish, Royal Blue (deep blue), Flora (lavender), Prince Henry (bronze), W. T. Ware (primrose), King of the Yellows (yellow) and Rossini (lemon and white). In English, Princess Juliana (large deep blue), King of the Blues (soft blue), Mer de Glace (white), Rosalie (rosy purple), La Marquise (rich purple) and Miss Ainsworth (blue veined). It is hard to stop when marking a bulb list

if one is about to spend one's own money, it is a hundred times harder when you are not even spending other people's money but only suggesting what they might go in for.

"You have never tried Camassias?"

"Well, how about a good form of *esculenta*, say Orion or Blue Queen, and a few *Leichtlinii*?"

Years ago I always used to have a few Feather Hyacinths (*Muscari comosum monstrosum*) in pots. They came in very handy for cutting. This is quite hardy, and the only object in giving it glass culture was that it made it look nicer. It acted, in fact, as a sort of vanity bag to the quaint inflorescence, which is neither fish, flesh, fowl nor good red herring. The whole looks like a mass of pinky mauve filaments which are having, as two men I met last week expressed it, "a happy day." They are all over the place, but whatever the cause of their eccentric behaviour, the whole effect is excellent. One tip to any good "Quocker-wodger" who is moved by curiosity to try some

himself—don't throw the bulbs away, as I have known people do, when the hard, little conical button which soon appears in the centre of the slender foliage looks as if it were an immovable fixture and that something has gone wrong. It is only its way. Its motto is "slow but sure." Later on it takes its time in disentangling itself, and one does not wonder at it when one compares the hard, solid-looking start with the finished article.

"Just a dozen or two, please, to try! Eighteenpence a dozen is not a very serious matter."

As the ladies were leaving the room the wife of the dearest old parson in the world turned to him and said, "Now, John, remember." When the door was closed he sighed and said, *sotto voce*, "And I was once a two bottle man!" The Editor stands over me as I keep writing on and on. Hand and index-finger are raised. His lips move. "Joseph, remember." Enough said!

JOSEPH JACOB.

HOLLIES—EVERGREEN AND DECIDUOUS

In our gardens the best known representatives of the genus Ilex are evergreen Hollies, varieties and hybrids of Ilex Aquifolium. Several deciduous species, however, are attractive in fruit, notably I. verticillata.

AMONG the evergreen trees and shrubs which are native of Britain, the Common Holly is the most valuable in garden, pleasure ground and park. Forming thick and much-branched specimens from the ground upwards to a height of 50 ft. or 60 ft., occasionally up to 80 ft., the Holly is exceedingly useful for shelter belts and screens. For thick, impenetrable hedges it surpasses even the Yew, being readily kept in shape with shears or secateurs. The Holly is not much favoured for topiary work, but is very well adapted for bold effects. Though growth in the first few years is rather slow, when once established in permanent positions, Common Holly makes very good annual growth both in height and width. Because of its slow early growth, well furnished Hollies for hedges may appear rather expensive, but the initial outlay is more than worth while in the provision of a good permanent hedge.

In addition to being a native of Britain, *Ilex Aquifolium* is a wild tree of the Continent and Western Asia. While a large number of the named varieties grown in our gardens are sports, or seedlings, resulting from a long period of cultivation and selection, others are hybrids between it and the Canary Island Holly, *I. platyphylla*, the Balearic Island Holly, *I. balearica* and probably other species. The varieties and hybrids, however, are so numerous, and are the result of so very many years cultivation and selection, that it is only possible to speculate as to the origin of a considerable number.

To supply foliage and colour in the pleasure grounds throughout the year the best green and variegated-leaved Hollies are well-nigh indispensable. In the shrubby borders, but best of all as specimens on the lawn, with the grass-green setting, the colours of the leaves are very attractive. A short list of the most distinct will suffice here, leaving those who desire a large selection to visit the collection at Kew, or a tree and shrub nursery specialising in Hollies.

Green-leaved: *camellæfolia*, very large dark green leaves, and large berries; *Hodginsii*, one of the best green Hollies, noted for its free berrying propensities; *Marnockii*, rich green broad leaves and large berries; *Mundyi*, a male Holly, with large spiny foliage; *Shepherdii*, raised in the Liverpool Botanic Gardens, where it is one of the

best evergreen shrubs, in what must be one of the most unsatisfactory climates in Britain to cultivate plants; *Wilsoni*, large dark green spiny leaves and red fruits.

Variegated-leaved: *argentea pendula*, Perry's Silver Weeping; *argentea regina*, Silver Queen; *aurea medio-picta*, Golden Milkmaid; *aurea regina*, Golden Queen; *Golden King*; *Lawsoniana*, yellow centres, edged with green.

Other distinct and interesting forms include *fructu-luteo*, yellow berries; *flavescens*, the Moonlight Holly, with leaves of a yellow shade; *terox*, the Hedgehog Holly, very spiny; *monstrosa*; *myrtifolia*, with narrow leaves; and *scotica*, a smooth-leaved Holly.

The varieties of hybrids of *I. Aquifolium* occupy such an important place among evergreens that we are apt to overlook quite a number of other ornamental species.

I. cornuta, the Horned Holly, is a native of China. This Holly is slow in growth, forming a compact evergreen bush, usually as wide as high.

I. crenata, the Japanese Holly, is a close-growing bush, of which there are several forms, major being, as the name suggests, more robust in growth, with black fruits, and *Mariesii*, a dwarf attractive shrub, in much demand for the rock garden.

I. opaca, the American Holly, is more interesting perhaps than attractive, compared with

the varieties of *I. Aquifolium*. It is a native of the Central and Eastern United States.

I. Pernyi is a Chinese Holly, first introduced by Mr. E. H. Wilson in 1900. It has small, dark green, spiny leaves, making an attractive specimen shrub of moderate size, though Mr. Wilson records occasional wild trees up to 50 ft. high. It has red berries, the seeds from which, as well as cuttings, provide ready means of increase. Another Holly introduced the same year from China by Mr. Wilson is *I. Fargesii*. It is well spoken of by several with whom plants are doing well, but with us the only plant growing at all freely is in shade and shelter.

I. platyphylla, the Canary Island Holly, is a free-growing evergreen with larger leaves than the Common Holly. Forms of this are var. *balearica*, with darker green leaves, from the Balearic Islands; var. *maderensis*, bright green; and *nigrescens* with rich dark green foliage.

THE DECIDUOUS HOLLIES.

This group of Hollies was originally separated from the evergreen section and known by the generic name of *Prinos*. The best known and most valued species for cultivation in our gardens is the American Winterberry, *Ilex (Prinos) verticillata*. It forms a much branched deciduous shrub, 6 ft. to 8 ft. or 10 ft. high, bearing in autumn quantities of sealing-wax red berries, which, as the leaves fall, become wonderfully attractive in the autumn sunlight. The berries of this Holly are very much used for decoration in the United States, taking the place of our evergreen Holly berries. The winters in U.S.A. are too severe for the culture of our native *I. Aquifolium*, except in the southern states.

THE GOLDEN-BERRIED HOLLY, *ILEX AQUIFOLIUM FRUCTU-LUTEO*.

LILIES IN THE GARDEN

(Continued from page 414.)

Other deciduous Hollies include *H. laevigata*, *monticola*, *serrata* and *decidua*, but except, perhaps, the last named, they are seldom seen outside botanical collections.

CULTIVATION.

While Hollies, in general, favour a moist loamy soil, they thrive in most soils and positions and are very good town shrubs. In common with other evergreen shrubs, spring, when new growth is beginning, is the best time for pruning. This may be fairly severe, if need be, for Hollies stand the knife, or saw, as well as most, and better than many, evergreens. August, when growth is practically finished for the year, is the best time to clip hedges and formal specimens on terraces and lawns. Shears are mostly used for reasons of expense or quickness, though if time permits secateurs should be employed for small formal specimens, to obtain the most satisfactory finish to the work.

Seeds, cuttings, layering and grafting provide ready means of increasing Hollies. The free-growing varieties root readily in a frame with slight bottom heat or a cold frame during late summer and early autumn. Others of the weaker growing varieties, interesting or novel, rather than ornamental forms, are more often increased by grafting under glass in early spring.

TRANSPLANTING.

Some care and attention is necessary successfully to transplant Hollies, especially of any considerable size. September and May are the best seasons for planting. Unless an unlimited supply of water is available if required, the transplanting on light soils is best done in September. Moved at that time they commence to make new roots during the autumn and with the winter rains are well settled in the new positions—an important matter if the following summer happens to be dry. On heavier ground, May, when new growth and root-activity has commenced, is usually favoured for moving. In addition to watering at the roots, newly planted Hollies should be sprayed morning and evening during dry weather.

It is desirable that the nursery ground where young Hollies are grown should be of a fairly heavy nature, so that they can be moved with good balls of soil attached to the roots. If the roots are cut to any considerable extent in transplanting, a somewhat corresponding amount of pruning and shortening of the longer branches is desirable. If a few of the older leaves fall off soon after planting, it may be taken as a good sign rather than otherwise. What the planter does not like to see is the leaves wither and hang.

Some comment was made last winter on the fact that Hollies were being transplanted in mid-winter at Kew. When, however, machines are available to transplant specimens weighing from a few hundredweight up to nine or ten tons of soil bodily with the plants, the season of planting scarcely needs consideration.

To the town dweller the Holly is best known by reason of its attractive berries for Christmas decoration. Among those unaware that Holly bushes are frequently (one might almost write usually) unisexual, the fact that berries are never seen on some Hollies gives rise to comment. To obtain good crops of fruits, bushes of both sexes must be planted; though, obviously, one would prefer a larger number of female forms. At the risk of repetition I sub-entend the names of a few well known varieties of each sex.

Male: *argentea regina*, *urea regina*, *Mundy*, *Wateriana*, *etlaclarensis* and *Donningtonensis*.

Female: *candellaria*, *flavescens*, *Hodginsii*, *Marnockii*, *Wilsoni* and *fructu-luteo*.

There are male and female trees of several varieties, which include *argentea medio-picta* and *urea medio-picta*. A. O.

CONTINUING the list of Lilies that should be included in the first collection to be planted, the section that must not be omitted is the Martagon. First, because it embraces many beautiful and distinct forms, but more because it is suitable for every garden.

Perhaps it will be as well to explain to the new cultivator that there is a whole section (or

or less regular intervals, and the whole spike thus forms a very graceful and "finished" looking arrangement.

Some of these species would not be recognised by those who only know the old purple Turk's-cap, which is the one offered by bulb merchants as *Lilium Martagon*. Old as it is, and it is said to be the oldest Lily in English gardens, it is well worth growing, as is also the pure white form *Lilium*

LILIUM MRS. R. O. BACKHOUSE OF MARTAGON X HANSONI PARENTAGE.

what experts have called a sub-genus) that comes under the title Martagon, and that the principal characteristic that distinguishes the species and varieties included therein from others is that all the flowers are reflexed. Some are more so than others, but they all belong to what are known as the Turk's-cap Lilies. The flowers are borne in a pendent or nodding position from the main stems, which form straight, erect spikes or racemes, varying in shape somewhat with the different species, but all bearing their flowers round the upper portion of the stem. In most cases the leaves are borne in whorls round the stem at more

Martagon album. Any soil suits them, and they are quite indifferent to lime. I cannot mention all the species and varieties that are included in the section, but the following will be quite sufficient for the average gardener to make a start with.

Lilium Hanson grows 3 ft. to 4 ft. high, sometimes rather more, bearing numerous golden yellow flowers spotted with black. It is a fine plant for the amateur to include in a trial collection because it is "safe." The first year after planting it often does not attain full stature, probably because it is often lifted and kept out of the ground too long, which obviously must

retard the root development. Never mind, it is not very good the first year, let it alone, and if the conditions are healthy it will come through all right subsequently and improve with time. It prefers a position where the soil is fairly strong and not too light, and certainly out of the direct sunshine. I have mentioned this first because in a way it has become the most important member of its section. As a parent of good varieties it has exercised a very potent influence. As long back as 1805 *dalhansonii* (now very scarce) received the award of merit of the R.H.S. This was a cross between *Hansonii* and *dalmaticum*, and was figured in *THE GARDEN* in July, 1893. By the way, *THE GARDEN* of those days used to give us wonderful coloured plates of any new or good plants that came before the public eye. Nothing quite up to the standard of those plates was ever published in any other popular periodical, but times have changed. *Dalhansonii* is a Lily with a fine upstanding stem bearing many flowers of rich deep purple, mingled with brown and growing 5ft. high. This and *Marhan*, a cross between the white *Martagon* and *Hansonii*, were two of the earliest successes as a parent. Since then there have been many, some of which are worthless, but the most recent and best of all are the crosses between the various *Martagons* and *Hansonii* raised by Mrs. Backhouse. These form almost a new race, with exceptionally sturdy, erect stems, bearing numerous flowers, and include varieties with buff, yellow, orange and bronze tinted flowers of great size, some exquisitely spotted, others almost self-coloured, others, again, delightfully suffused with pink, rose, brown, apricot and many subtle intermediate tints. They are robust, vigorous plants and quite "safe" even in the hands of the veriest amateur. Mrs. R. O. Backhouse and Sutton Court were the two first of these to be introduced, succeeded by *Golden Orb*, and there are several others now obtainable.

Of all the "Turk's-caps" the *Chalcedonian* scarlet *Martagon* (*Lilium chalcedonicum*) is the most startling on account of its colour, a brilliant vivid scarlet of fiery intensity. It has stood the test of time for several hundred years in English gardens and is still unique so far as colour is concerned. There is a variety called *maculatum* on account of the black spots on the brilliant scarlet flowers, and this is the variety that should be planted whenever it can be obtained. It is more robust than the type, grows taller, and has been known to survive when, for some undetermined cause, the latter has died out or failed to do as well as it should. As, however, both forms are frequently to be found in old cottage gardens, probably the direct descendants of those described by Parkinson and Linnæus, they can be well recommended on the score of hardiness. They can be found doing well in practically all sorts of soils. There are other varieties one reads about but rarely sees. A purple form is said to have existed at one time, but I think it is unknown now. This is one of the Lilies that does not obey the general rule among the *Martagons*, and bear its leaves in whorls, more or less regularly spaced up the stem.

The mention of *L. chalcedonicum* suggests another very excellent garden Lily, *excelsum*, perhaps better, or more familiarly known as *testaceum*. Not that from the ordinary gardener's point of view there is a very close resemblance between the two. In fact, the casual observer would scarcely attribute the parentage of *testaceum* to *chalcedonicum*. At the same time a more intimate study reveals many points of similarity, particularly in the shape of the flower and the way it is carried on the stem, and also in the arrangement of the foliage. It is, indeed, a fine Lily, and should certainly be among those that

THE VERY HANDSOME WHITE FORM OF THE MARTAGON,
LILIAM MARTAGON ALBUM.

even the novice plants. Very tall, even among Lilies, of soft buff yellow, with a faint suffusion of reddish orange in its colour composition, it is quite unique in this respect. It is a vigorous grower and does well in most soils, and is another Lily that does not object to lime. No one can vouch for the origin of this Lily, although all the evidence goes to prove it was the result of a cross between the Scarlet *Chalcedony* and *Madonna* Lilies. It is, however, a curious fact that this startling innovation in the Lily world appears to have been quite unnoticed at the time, as no one appears to know where it originated.

Another good Lily that comes within the *Martagon* section is *colchicum*, a far more convenient name for the plant than the one by which it is generally known (*monodelphum Szovitzianum*). This has clear pale yellow flowers with black spots. It will, under favourable conditions, grow 5ft. high, is very strongly scented and, in short, a Lily for every garden.

There are three very beautiful Lilies that are classed as *Martagons* that are more suitable for the damper spots in the garden and, indeed, succeed well by the side of a stream or pond. *Lilium canadense* is variable in colour from pure yellow to deep orange, grows about 3ft. in height, and is very dainty. *Lilium pardalinum* grows much

taller, often 5ft. or 6ft., has orange and crimson flowers with dark spots, and develops large numbers of its beautiful flowers (often twenty or more buds and flowers) on the same stem; this also is variable in colour, and there are several good varieties. *Lilium superbum*, taller still and with exquisitely graceful flowers of orange shaded to crimson, very distinctly spotted, is the finest of the North American Bog Lilies.

These are a few of the Turk's-cap Lilies, and no one will regret giving them a trial because they are among the "safe" species. Even those that like moisture will thrive in any good garden soil that is not too hot and dry.

I suppose few people, wandering through an English garden, realise what a cosmopolitan affair it is. Nothing except the language we speak, in modern life, is so indicative of the world-wide energies of the race. Foreign pictures are collected and remain among us as examples of foreign art. The music of the world's composers comes and stays, as individual effort. These undoubtedly exercise an influence on home products, but never, as it were, become naturalised and take root in the nation's being. Words—and plants, alone do this. The newly imported plants of our gardens of

one generation, become the garden commonplaces of the next, and to the multitude the occupants of the flower border are just garden flowers, with never a thought of their origin. In two generations the hybridist has mingled the characteristics of species collected from widely distributed areas to such an extent that they cease to have any nationality but our own. Perhaps the most startling exception to this rule is in the way the Japanese Lilies have remained Japanese. One would almost conclude that the words of Kipling, "For East is East and West is West, and never the twain shall meet," could be extended from their social aspect to the garden. Yet nothing has exercised a more potent influence on modern gardening than the opening up of Japan, with its free intercourse of commerce, during the nineteenth century, and perhaps the richest contributions Japan has made to English gardens are its Lilies. The hybridist at home has done curiously little towards mixing them with other species.

Particulars of these Japanese Lilies and the remainder of this list of sorts for the garden, together with a few remarks on raising many of them from seeds—an extremely interesting phase of gardening—must be reserved for a concluding article.

GEO. DILLSTONE

(To be concluded.)

ABOUT STRAWBERRY CULTURE

THE cultivation of the Strawberry needs care and skill. This is generally regarded as the most difficult of the small fruits to manage. The first necessity is a suitable soil, and experienced growers are agreed that a heavy loam gives the most consistent returns. In soils of a light nature growth is often suspended by drought. When preparing the ground it is well to remember that the plantation should endure for three years. Thoroughness and liberality, therefore, should be the motto. I believe in double digging or trenching, according to the nature of the subsoil. Good farmyard manure should be mixed with both spits at the rate of half a ton per 100 sq. yds. The ground should be lightly trod and raked ready for the reception of the plants not later than the latter end of September—the earlier the better. Each plant should be set firmly and care taken not to bury the crown. A small crop of fruit will be borne the first summer after planting.

Straw should be spread beneath the berries when they are about the size of marbles, to keep them clean. I have heard growers say that it is a mistake to fruit Strawberries the first year after planting. My own judgment, after a careful test, is the reverse. All runners not required for the purpose of propagation should be removed at the earliest practicable date, and an abundant crop will be carried the second year. After it has been gathered, the oldest leaves should be removed. They have reached an age when they cease to function well and the crowns ripen better in their absence. It is wiser, therefore, to remove them. Runners should also be cleared away from the bed. In the third year the plants will give a profitable return. After that they cease to be worth the land occupied.

The above routine will, of course, be commonplace to experienced gardeners. It is necessary to have successional batches of Strawberries or there will be a break in the supply of fruit. The accepted and sound custom is to provide three batches of one, two and three years old plants respectively. Runners should be taken from one year old plants. It is essential to use some care in the selection of this propagating material. Runners from "blind" or fruitless plants are unsuitable. They are almost certain to bear the sterile character of their parents. Choice should also fall upon the first runners, because they are known to possess a strong constitution. There are two methods of propagation. One consists of inserting the runners in 3in. pots. A light potting compost should be used. The receptacles are plunged into the soil to keep them level and reduce watering. The creeping stem of the young plant is secured in position by a stone or wooden peg. This method of propagation is considered best because the plantlet receives parental support until it is established. The attachment is then severed and the stock is transferred to its permanent quarters at the appointed time. The alternative form of propagation is to detach the runners from their parents and plant them 6ins. apart in nursery beds. Where labour is scarce this is the procedure adopted, less watering being required. There are many varieties of the Strawberry. Royal Sovereign is the one most grown. The fruits are early, of fair flavour and they travel well. The Laxton is rather later. It is a good variety, very similar to Royal Sovereign in appearance, but not quite so heavy a cropper. Sir Joseph Paxton is a useful late kind, bearing very large berries. The above varieties, owing to their vigour, should be planted

in rows 1ft. apart, the plants in the rows 1ft. 6ins. I should like to make mention of Bedford Champion. It is a most consistent late-fruiting variety. Not

being very vigorous in growth, it finds ample accommodation in rows 2ft. apart and 1ft. from plant to plant. GEO. H. COPLEY.

DARWIN TULIPS AT LOWDHAM

THE Editor paid a visit this year to the Lowdham Nurseries of Messrs. J. R. Pearson and Sons, just when the Darwin and Cottage Tulips were at the height of their glory. The nursery beds are a wonderful sight, of course, and it is interesting to see somewhat similar varieties growing side by side, but to institute a reliable comparison, it would be necessary to see them several seasons running. All who have experience of these very attractive sections will agree that both the Darwin and Cottage varieties vary very considerably according to climatic conditions and that the supreme variety of one season is often somewhat "under the weather" the next, while another sort of, possibly, similar colouring shews a corresponding improvement.

The amateur visiting these tulip fields for the first time will probably suffer at first a shock of disappointment, for late-flowering Tulips look incomparably finer in clumps of moderate size than they do as mere chequered masses of colour in row upon row of oblong beds. This first disappointment over, enthusiasm will come, for they are extraordinarily well grown and marvellously free from rogues.

Among the Darwins the eye, as usual, picked out the popular Farncombe Sanders, of vivid

the shining rose Pride of Haarlem. Certainly the great Dutch bulb-growing centre has reason to be proud of this splendid variety!

Now for a few words about the paler coloured sorts! Clara Butt inevitably catches the eye in this section and at its best it is of beautiful colour and excellent form. The mauve shaded Rev. Ewbank also attracts and the practically pure white White Queen gives needed variety. A good breadth of the rather dowdy William Copland reminds us how well this variety forces and how really beautiful it is under glass. To those who dislike the slight staining of White Queen, L'Ingénue, the white of which is delicately but decisively suffused with rose, will appeal strongly.

There is a multitude of good dark purple and maroon Darwins. Far too many, most people will think. Andrea Doria, Faust, Frans Hals and Leonardo da Vinci, are some of the best. The Bishop, rich purple shot with lilac, is distinct and of good form, while La Tulip Noire, which almost lives up to its name, must not be overlooked. It is, indeed, very effective associated with some of the salmon Darwins and orange Cottage varieties, such as Orange King and La Merveille; the latter, one of the most glorious of all the varieties on view at Lowdham—the colour may best be described

SOME OF THE MAY-FLOWERING TULIPS.

cherry-red colouring, still, perhaps, the best all-round Darwin in cultivation. The large and handsome deep rose Petrus Hondius, stout-stemmed and compact, also made a lovely splash of colour, but, of course, the varieties with orange or salmon shading kill pure rose tones if allowed to approach them at all nearly. Such an one is to be found in Prince of the Netherlands, not very dissimilar to Farncombe Sanders in colour, though darker and not so bright, and distinctly larger in flower. Even more like Farncombe Sanders is Professor Rawenhoff, but this year, at any rate, "Farncombe" had the advantage. The rich deep red Bartigon, a very sturdy grower also attracted favourable comment. Mr. Duncan Pearson recommends this especially for forcing. Nauticus, deep glowing rose, with a dark violet base, is another showy sort, also useful for pot work, and the same may be said of

(very inadequately) as salmon shot with vermillion. Among late-flowering Tulips outside the Darwin fold, there are several other indispensables, such as the splendid Gesneriana major, the almost equally valuable Gesneriana lutea, the useful Inglescombe Yellow, the clean-coloured Inglescombe Pink and the glorious Mrs. Moon. All these and many more we saw at Lowdham, all in the prime of vigour, and studied and compared them until our eyes fairly ached with the riot of colour.

Only the Tulips were in blossom on the occasion of our visit, but we were equally impressed by the many acres of Narcissi, including numbers of the very newest and choicest. They have a very short way with eelworm at Lowdham. New stocks are grown apart and, if they shew any signs of this dreaded pest, the bulbs are treated without

loss of time to the hot-water cure. The results certainly justify the trouble; it is impossible to imagine a finer or healthier lot of plants and most readers need no reminding of the quality of the bulbs sent out, year by year, by this well known firm.

Fruit trees and Roses, Messrs. Pearson's other specialties, are grown equally well and splendid breadths of established market trees shew just

how these should be pruned to give the best results. The thousands upon thousands of dwarf Roses were not sufficiently forward to enable one to judge what the plants would be like by autumn, but they promised well. An experimental plot of standards, however, worked upon a new stock attracted attention. This stock appeared to be of rugosa kindred and we shall be interested to hear how it turns out.

THE RIBBON WOOD

LAST season and this I have had in flower in my garden a shrub that has given me infinite pleasure, partly because of its exceptional beauty, and partly because of the pleasant memories associated with

a plant which I have known affectionately for many years and have seen growing, as all growing plants are seen to best advantage, in its native soil and country. The shrub in question is *Plagianthus Lyallii*. I do not know, though I dare say I ought to know, what particular plant-loving Lyall has had his name associated with this fine tree; but, if ghosts take account of such considerations, the ghost of Lyall must be proud to remember that his name is inseparably linked with two of the most lovely plants of the New Zealand flora, one, *Ranunculus Lyallii*, the stateliest of Buttercups, and the other, *Plagianthus Lyallii*, a Mallow, as beautiful in its way as the Buttercup, though not, perhaps, so rare, and certainly not so difficult. I am not sure whether the generic name has not been changed by botanists from *Plagianthus* to *Hoheria*, or possibly it is *vice versa*. Anyhow, to me it has always been *Plagianthus*, and will be to the end of the chapter, unless a pretty English name is preferred, in which case we may call it "Ribbon Wood" or "Lace Bark," the names by which it is called by Dominionists unversed in botany, in allusion to the tough and lacy inner bark used by women-folk in early days for various millinery purposes. Of the two names I believe Ribbon Wood is the more generally used.

Among British trees the nearest analogue of the Ribbon Wood is perhaps the Cherry. If there is anything in trees more beautiful than a Cherry or Gean tree in bloom I do not know it; and when I say that what a well grown Cherry tree is to April a well grown Ribbon Wood is to July, I mean to give the New Zealand tree the warmest praise I can devise. But though both trees give the

general effect of freshly fallen snowflakes, it must not be supposed that the New Zealand plant merely repeats the Cherry, from which, on the contrary, it differs materially in branch, bark and foliage, as well as in the character of the

PLAGIANTHUS LYALLII IN EDINBURGH BOTANIC GARDEN.

individual blossom, which is essentially malvaceous, resembling somewhat that of the white *Malva moschata*, but without the hard lustre of that Mallow. The leaf of the Ribbon Wood is a flattened spear-head, with serrated edges, somewhat like the leaf of certain Poplars, and is attached to the twig by a somewhat long footstalk, which should make it, one would think, as tremulous to the wind as the leaf of the Aspen. The colour of the foliage is peculiar, a light olive, and is an effective setting for the blossoms, which spring from the axils of the leaves in clusters more or less dense, quite a different fashion of inflorescence from the spur system of the Cherry. The Ribbon Wood is notably a "twiggy" plant (almost what botanists would call "sarmentous"), and this infinity of twigs, each carrying, midway of its length, a dense cluster of axillary blossoms, gives the tree the well furnished appearance it has in July.

How hardy the Ribbon Wood is in this country I cannot exactly say. My own tree, still young and of modest size, has stood unharmed here (in Somerset) for four or five years, but it grows against a south wall. From my knowledge of the plant in its native habitats, however, I should expect it to stand our winters quite in the open in all but exceptionally high and bleak situations. The distribution of the *Plagianthus* in New Zealand is peculiar and interesting. It is exclusively confined to the Middle Island (say lat. 42-45S.), and there to the western side of the lofty alpine range which forms the axis of the island, being found seldom, if at all, on the eastern side. It seems to prefer the moist conditions of subalpine forest country, though its area extends from sea-level to an altitude of 4,000ft., at which latter elevation it is deciduous and, needless to say, has to endure a sufficiently low winter temperature. Where I have myself seen *Plagianthus Lyallii* most luxuriant and abundant has been at elevations midway, I should think, between the sea and the alpine levels, to the west of the picturesque Otira Gorge, for instance, on what is known as the "West Coast Road." But in my memory no locality is so closely associated with the *Plagianthus* as the high plateau in front of the Sutherland Falls, some fourteen miles from the head of Milford Sound, in Western Otago. Though the sight of mountains, near or far, sets my nerves tingling, I am not particularly susceptible to the lure of waterfalls. Still, a fall that is twelve times as high as Niagara (the "official" height is 1,004ft.) is surely something. It is true that the volume of water is by comparison inconsiderable. From a cliff 2,000ft. high, drop 600yds. of Brussels lace, tucking it up here on some projecting jag, splitting it up there, flouncing it out now and then with crinoline, at rare intervals letting it fall in solid sheets, and you would have something indistinguishable from the Sutherland Falls, except for the absence of spray and pother at the foot. Still, though not Niagara, the Falls were worth going fourteen miles to see. For, after all, what is fourteen miles? Especially when one is rowed four of the fourteen up a lovely lake and tramps the rest through scenery bewildering in its diversity—mountain, valley, river, shady forest, with such filmy Ferns and such mosses underfoot as I shall never see again except in dreams. Though always an interested observer of vegetation, especially if it is at all new, I retain but few individual impressions of the countless interesting things seen on that memorable tramp, my memory having room only for one distinct picture—the lovely grove of flowering Ribbon Wood through which one had finally to pass to the front of the Falls.

SOMERS.

THE MEXICAN WHITE PINE

PINUS AYACAHUITE, the Mexican White Pine, especially without its cones, may very easily be mistaken for the commoner Himalayan *P. excelsa*, which, to our knowledge, has occasionally been supplied for it. It may, however, always be distinguished by its young shoots being covered with a minute down. Those of *P. excelsa* are perfectly smooth. The cones also are very similar in size and shape, but are always to be recognised, in that the scales nearest the stalk are curled back towards it, as they never are in *P. excelsa*. For the rest, the Mexican White Pine is a handsome tree with its leaves in bundles of five. It is quite hardy in the Home Counties, but likes the milder conditions of the extreme South and West, where its less hardy variety *Veitchiana*, with cones up to 18ins. in length, also thrives. The cones in the typical form are usually 6ins. to 12ins. long.

CORRESPONDENCE

GOOSEBERRY SAWFLY.

[Our issue of August 11, ways of overcoming this pest are described, but not my method. Many years ago, year by year our bushes were cleared of leaves, and we used to pick the "caterpillars" off. I noticed when the men were doing this that many of the caterpillars used to fall off. So I stopped the work and had a ring of soot put round close to the stem of each tree, and every morning each bush was shaken with a forked stick. The "caterpillars" fell off and could not get back, and so none came to maturity, and the next year we had none and have had none since. This may interest your readers who are troubled with this pest.—THACKRAY TURNER.]

GOOSEBERRY SAWFLY AND SILVERLEAF.

I HAVE been very interested in reading the article in last week's GARDEN on the gooseberry sawfly, also its prevention and remedies. May I give a very simple and, I find, certain preventive — i.e., plant a single Broad Bean between each Gooseberry bush, and the sawfly will trouble you no more. I was told of the remedy years ago, before we had a garden, and know no "reason why," merely the results. In 1915 I tried to persuade our gardener to do this (we had just come to a country rectory with a large garden and he was taken on with the garden, having worked for several rectors before), but like the

"Waters of Jordan," it was far too simple a remedy; however, the following year, when gardeners were not to be had, I ran the garden with the help of a boy and we tried the Broad Bean remedy with the greatest success, and every year, now that our original gardener is back again, the Beans are planted among the Gooseberries as a matter of course, and he talks of how "we" keep our Gooseberries free from caterpillar!

I should very much like to add my thanks to your correspondent of last year for the valuable hints on the cure of silver leaf. In May, 1922, we uprooted and burnt a splendid Victoria Plum which was badly affected and cut away more than half a Czar, which was also badly touched; then in July I saw a "cure" in THE GARDEN; we immediately treated the Czar, and at intervals during the autumn and winter, with the result that this year the half of the tree that was left is covered with fruit, the foliage is healthy and the tree starting to make good the part that was cut away.—C. E. WILLIAMS, N. Devon.

THE CARPENTERIA.

I ENCLOSE a photograph of *Carpenteria californica* which you may care to reproduce in THE GARDEN. It is one of the most beautiful of evergreen shrubs, and seems to be but little known. I have three plants, all grown against the house and walls, but they get no other protection of any kind. We are 450ft. above sea-level, and although in severe winters the ends of some projecting shoots get frosted, they are cut off without any hurt to the plants and all the plants flower freely every season. I am surprised it is not generally known and much more grown. I know of only one other plant in this district—the South-East of Scotland.—A. R.

THE BEST SIX BEDDING ROSES.

I THINK it would interest a great many of your readers if you could induce some of those learned in Roses to give lists of best bedding Roses. If you could find space, perhaps you could make the suggestion in your "Correspondence." I derived considerable assistance from a list published in your columns in reply to a similar request. To start it I would suggest Hadley, Mrs. H. Morse, Christine, Mrs. C. V. Haworth, The Queen Alexandra and Mme. Butterfly.—C. ECHLIN GERABLY.

THE GENTIANELLA.

THE illustration gives a portion of a large bank of this Gentian which has not been moved for many years. It will stand in one position for a long time if it has a good dressing of some fertiliser as soon as it has finished flowering and also plenty of water in the growing season.—W. A. MINER.

PLANT NAMES.

IN Sir Herbert Maxwell's "Memories of the Months" (2nd Series, page 250) I read that *Monarda didyma* is "first cousin of the Bergamot often seen in old-fashioned parterres." Only cousin? I thought *Monarda didyma* was the Bergamot. What, then, is the Bergamot often seen in old-fashioned parterres? Possibly *Monarda fistulosa*, which I do not possess. Incidentally, I note that, on the opposite page to that already quoted, Sir Herbert Maxwell, speaking in praise of *Gracilima littoralis*, assumes that this plant has no English name. This tree is native to New Zealand and very common there, where few know it by its scientific name but all call it "Broad-leaf." *Chorva ternata* is also, on the same page, said to have no English name. In "The English

CARPENTERIA CALIFORNICA IN SOUTH-EASTERN SCOTLAND.

A GOOD MASS OF THE GENTIANELLA, GENTIANA GENTIANELLA.

Flower Garden" the name "Mexican Orange Flower" is given. I can say nothing as to the currency of the name. Possibly it was invented by the author who uses it. Anyhow "Mexican Orange" is not a bad name. What is it called. I wonder, in Mexico?—SOMERS.

AN UNCOMMON ANNUAL.

THAT interesting plant *Martynia proboscidea* is a native of Louisiana, seeds having been introduced into France during the eighteenth century. *Martynia* is a half-hardy annual, and although of no great garden value, is worth growing for its large purple or whitish flowers and curious fruits. Each of the latter is provided with two large curved hooks, which probably serve as an aid to seed distribution. The fruits do not appear to set freely unless the flowers are hand-pollinated. This can be done with ease on account of the large size of the flowers and the abundance of pollen they produce.—N. K. G.

THE SPRING STAR FLOWER.

I WAS pleased to see N. H. P.'s remarks about that inexpensive yet pretty bulbous plant, which few amateurs appear to cultivate—the Spring Star Flower, *Triteleia uniflora*, also known, by the way, as *Milla uniflora* and *Brodiaea uniflora*. It is truly a delightful spring flower, especially in considerable quantity, and when growing in grass is lovely indeed. The writer knew a garden on the outskirts of Edinburgh where it had been planted in the grass for years and had seeded freely and spread to a gravel drive where it looked equally charming in its informal array, spreading over the green turf and gravel and opening out to the sunshine of spring. Its drawback is that it prefers to be in the sun as its real beauty is not fully revealed until it responds to the wooing of King Sol. It has given rise to at least two varieties, alba and violacea. Both are more expensive than the type, and it is doubtful if they are as useful as it is. Alba is white and violacea has blooms of a porcelain blue. From the reference given above to an Edinburgh garden it may be gathered that *Triteleia uniflora* is hardy in most places. It may be purchased in autumn with the other bulbs and planted at a depth of about 2 ins. Where it established itself and seeds freely it is exquisite in the grass and it may also, as your illustration shews (page 416), be planted in clumps in the rock garden as well as in the border. It comes from Buenos Ayres and is one of the few plants coming from there which may be considered hardy.—SCOT.

FOR THE COOL GREENHOUSE.

THE attention of bulb-lovers possessed of an alpine house which is slightly heated, or a cool greenhouse, is directed to the Chilean Blue *Orocus*, *Tecophilæa cyanocrocus*, a real jewel among

bulbs, and quite a rare plant in gardens. It has been recommended for outdoor culture, but, unless in specially favoured parts of the kingdom, it is

A FLOWERING SPRAY OF MARTYNIA PROBOSCIDEA.

not hardy enough to risk out of doors. Some succeed with it in a frame or under a handlight in a warm, sunny spot, but even if it should escape the ravages of slugs there, it is safer when grown in pots, planted 2 ins. to 3 ins. deep in light, rich soil in October, and sparingly watered at first (giving more when the season advances) and grown on in a cool house, where it should bloom in March or April. It is an exquisite flower, crocus-like in appearance, and of a lovely blue, with a white throat. It is, unfortunately, a rare bulb in commerce and seems to become scarcer in the trade, but it is still offered by some dealers. There are several varieties some of which are not on offer, but one called T. c. violacea, with violet-blue flowers, is available from some sources.—S. ARNOTT.

TULIPS IN GRASS.

ON page 419 of THE GARDEN for August 11, Mr. Briscoe, in his notes in "Gardening of the Week," when writing about bulbs in grass, says, "Daffodils, Tulips, Scillas, Snowdrops, Crocuses, etc., are so beautiful when naturalised in grass. . . . They produce a wealth of bloom when established and increase in numbers." May I ask him, first, which Scillas and which Crocuses does he refer to? My experience with *Scilla campanulata* varieties is that they do not increase in numbers in grass, and with regard to the old yellow Dutch Crocuses that I have grown it is much the same. Probably, other Dutch varieties would sow themselves and so produce and increase in the course of time, but these I have not tried. Secondly, may I ask him how he has got Tulips of any kind to give displays of bloom

every year and to increase in numbers without giving any "further trouble when once planted"? For the last twenty years or more I have been trying to solve this problem myself, and I have asked by word of mouth and through the Press how the trick can be done, and I am as far off as ever from a satisfactory solution. But one is always ready to learn, and if Mr. Briscoe would only tell us in the columns of THE GARDEN how this consummation can be achieved, of having Tulips to succeed in grass like Daffodils, he would confer a very great favour upon myself and upon many owners of parks, fields and lawns who would like to have a little barbaric splendour in their surroundings once a year at any rate. I have got an envelope of replies to a question I once asked in THE GARDEN on this subject but they neither gave me help nor hope.—JOSEPH JACOB.

CURRENT WORK AMONG CHRYSANTHEMUMS

If given good treatment these plants will afford cultivators a lot of pleasure both under glass and in flower borders throughout the autumn and early winter months.

THE season has come round once more when interest in these plants is deepened through the appearance of thousands of flower buds in nearly every garden where the blossoms are appreciated. The harvest is now approaching; it is the result of nearly twelve months continuous labour.

PLANTS IN BORDERS need judicious support against the strong south-west winds; this support should be afforded in such a way that very little of the stick or branch will be noticed; neither should the natural shape of the bush be altered. If tightly tied the plants will resemble sheaves or faggots of wood and look very bad in the border. Having seen to the branches the next thing to do is to examine the border to give copious supplies of water where necessary and also of liquid manure, to apply a mulch of half-rotted manure, wood ashes, spare soil from an old heap, and, in ornamental borders near the dwelling house, leaf-soil or coconut-fibre. These attentions are worth while as their effect will be substantial and pleasing.

PLANTS IN POTS.—These have needed very close watching throughout the summer months on account of the great heat and prolonged drought. It has, however, been possible to feed the plants regularly since the early part of July. The regular use of soot sprinkled about the plants and the occasional syringing of the foliage with soot water have, combined, had the effect of clearing the leaves of the maggot, also of green and black fly. Cultivators must watch closely for the very tiny thin grubs, caterpillar-shaped, rolled up in the tip leaves, as they destroy the point of growth containing the precious buds. To keep the plants clear of these pests the shoots should be examined every other day. Throughout August and the first half of September, of course, buds will be "taken" where large blooms are required. The work of "taking" them should be done gradually, removing the side shoots or, in the case of terminals, the side buds, a few each day till only the selected bud is left. Feeding at every watering-time may be the rule, all stimulants being applied in a weak state, as strong doses less seldom given, do harm, not good. If rust or mildew appears, syringe the leaves, especially the undersides, with sulphide of potassium, a quarter of an ounce dissolved in a gallon of water—two applications being better than one. Place the plants under glass just before the buds open and the colour of the petals can be seen. GEORGE GARNER.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Cabbages. When the plants in the seed-bed are large enough, they should be transferred to their final quarters. The small-growing varieties should be set out 1 ft. apart, but the larger kinds will need almost twice the amount of space. A rich soil is not required, and the onion-bed will be found most suitable for this crop, while a piece of ground recently occupied by Potatoes may also be used. Water the roots at planting-time, and if the seed-bed is very firm, the young plants should be lifted with a fork to prevent undue injury to the roots. Where slugs are numerous, dust the plantation with lime, and employ the hoe at frequent intervals to destroy weeds and to maintain a fine tilth. Another batch of plants should be put out a fortnight or three weeks hence.

Turnips should be thinned as the necessity arises, and the soil between the rows loosened with the hoe. A dusting of well-seasoned soot is beneficial.

Spinach.—The final sowing of this vegetable should be made during the next ten days, and earlier sowings should be kept clear of weeds, while the young plants may be thinned to 6 ins.

Onions.—The bulbs from the plants raised early in the year are showing signs of maturity, and those that still possess strong green tops should be bent over so that the leaves touch the ground. The bulbs should be thoroughly ripened before they are stored, and there is nothing better than a dry, open shed in which to store them. Damp is usually the cause of decay in Onions and, when storing them, it should be borne in mind that ordinary frost is not harmful.

Vegetable Marrows.—These are producing good crops, and the roots may be assisted with liquid manure or a reliable fertiliser. Cut the fruits before they get too large, and remove any dead leaves and worn-out shoots.

The Flower Garden.

Dahlias should be provided with stout stakes and the growths tied up with strong twine, or they will be broken down with heavy rain and wind. If the weather is dry, give them a mulching of manure. The new variety *Coltness Gem* is a fine thing, and it should certainly be given a trial by all Dahlia-lovers.

Roses.—On some varieties mildew has made its appearance, and where this is present the foliage should be sprayed with one of the specifics for mildew or with liver of sulphur, 1 oz. to 5 gallons of soft water.

Chrysanthemums.—These will need supports to keep the stems in an upright position, or later on they will be useless for cutting. A little disbudding will be necessary with the kinds that bloom during October.

Bedding Plants.—Such plants as Wallflower, Polyanthus, Forget-me-not, Aubrietia, Arabis and Alyssum are making nice sturdy specimens. Hoe the soil frequently between the lines and keep the ground free from weeds.

Eremuri.—These stately plants are best left undisturbed for several years, but where they have formed a number of crowns it will pay to divide a few plants. Now that the foliage has died down such work may be carried out, or new plants may be purchased. A well-drained position is necessary, and the crowns should be several inches below the surface. The young growth and flower-spikes in their early stages require a little protection from spring frosts.

Lilium candidum.—This beautiful old Lily is often seen in excellent condition in cottage gardens, while in larger establishments it is often but sparsely represented. Now is a suitable time to plant the bulbs, or lift and divide existing clumps. Deep planting should be avoided, and where the soil is of a heavy, retentive nature plenty of sharp sand should be added.

The Hardy Fruit Garden.

Morello Cherries are exceptionally hardy and rarely fail to produce a crop and, moreover, they flourish where many other fruits would linger. A north wall is an ideal spot for them, and although they are usually associated with such a position, they will nevertheless thrive as pyramids and bushes if planted in the cooler parts of the garden. Early in the season the necessary disbudding was, no doubt, carried out, so directly the trees are cleared of their fruit any

further pruning may be done. Remove the old wood that has fruited and tie in enough of the current season's growth to cover the wall. The main branches should be retained unless they are unhealthy. By pruning at this season the growth has a better chance of being ripened, and it also relieves the pressure of work later on. When the operation is completed give the roots a thorough soaking of water if the soil is dry.

The Fruit Quarters.—Here it will be necessary to use the hoe freely to get rid of all weeds before the winter and prevent any from producing seeds. Any dead branches should be cut out and burnt.

Fruits Under Glass.

Vine Borders. From time to time it is necessary to provide the Vine borders with fresh soil, the old rooting material eventually becoming exhausted. In some instances there is room for additions to the Vine border, and the best time to provide new soil is soon after the Grapes have been cleared. An addition of 2 in. is ample, but where the border is already filled it will be necessary to take out a trench and remove the old soil until live roots are found. It should then be replaced with good turfy loam chopped up with a spade, adding ½ in. bones to the extent of 1 cwt. to the cartload and one or two barrowloads of mortar rubble. Well mix the soil a few days before it is needed and protect it from heavy rains. Care should be taken not to injure the roots.

T. W. BRISCOL

(Gardener to W. R. Lysaght, Esq.,
Castleford, Chepstow, Gloucester.)

FOR NORTHERN GARDENS.

The Kitchen Garden.

Shallots are very popular with amateurs, who often fail with the cultivation of Onions. Shallots should now be ripe, or nearly so, and may be lifted, bunched and hung up in a dry airy structure, or even in the open for a time, unless the weather proves wet.

Herbs.—Mint, Sage, Thyme and other useful herbs should now be cut, selecting a dry day for the operation. Tie them together in moderate sized bunches and hang them up in a dry, airy structure to dry.

Onions.—Autumn-sown Onions should now be ready for harvesting. It is a good plan to arrange them along the sides of the pathway or on some other hard surface for a fortnight or so, prior to storing them. Spring-sown Onions will also be showing signs of ripening, and any thick necks which still stand erect should be flattened by gentle pressure with a garden basket; this will arrest all attempts at further development and compel them to fall into line with their neighbours.

Leeks will now be growing freely and will respond to weekly attentions with a little stimulant of a nitrogenous nature. Finely powdered fowl manure suits them admirably; it should be watered in if the weather proves dry. Keep the Dutch hoe moving freely among the crop.

The Hardy Fruit Garden.

Morello Cherries.—It is inadvisable to give attention to the wood now, until the fruit has been picked, and such attentions should not be necessary if it was given as the shoots developed. If a portion of this crop is double netted it will prolong its season of utility very considerably.

Young Trees.—Attend to the training of young fruit trees, more especially those on walls or espaliers; the young shoots can be much more easily manipulated now, while the wood is green and supple, than later on when it becomes ripe and hard. Keep a sharp look-out for woolly aphis and should it appear, paint the affected parts with paraffin or methylated spirit. If the soil is lacking in moisture, apply a liberal supply of water, as the young trees suffer from drought much more readily than well-established ones. After watering, stir the surface of the soil with the hoe, unless the trees have been mulched. If not already done it will be an advantage to mulch them even now.

The Flower Garden.

Dahlias should now be making a brave show; go over the plants and give them a final tying for the season; do not tie them up too tightly, rather loop them up into a natural position quite loosely. Remove all spent blooms and examine the earwig traps frequently. Water the plants liberally should drought occur.

Gladioli. Go over the plants and readjust the ties if the plants are becoming "hanked," giving additional ties as the plants develop. As the stems and foliage of the early-flowering varieties become ripe they may be cut over and if the plants are becoming "blanky," the whole should be lifted and the corns cleaned and graded prior to being replanted a few weeks hence. On soils where these early sorts do well the smaller corns may be planted in nursery lines to develop, but on less suitable soils the smaller ones should be discarded, as they are not worth troubling about.

Delphiniums.—Those who have raised seedlings should now plant them out about 9 ins. apart in the reserve garden, where they may remain until spring, when they should be planted out into their flowering quarters.

The Wild Garden.

General Work.—Those who possess a wild garden should give it a general overhaul and clean up before the rush of autumn work comes on. The grass should be cut with a scythe or reaping hook. The pruning knife or hedge bill may have to be applied to certain over-vigorous plants and spent blossoms should be cut away. The hoe, or more likely the digging fork or cultivator, should be brought into play on the parts that come under the spade.

CHAS. COMFORT.

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian.)

GREENHOUSE AND CONSERVATORY.

Nerines that have been dried off for the summer start flowering towards the end of August, usually commencing with *N. Fothergillii* major, many of the hybrids following later on. Nerines do not require frequent repotting—in fact, they produce their flowers with the greatest freedom when the pots are crowded with bulbs—but if repotting is necessary, it is best done at this time. Plants in bad condition should have all the old soil shaken away, and all dead and decaying roots, as well as the decayed base of the bulb, carefully removed. The compost should consist of a good rich medium loam to which a little leaf-soil has been added, also a ½ in. potful of fine bone-meal to every bushel of soil, with enough clean coarse sand or old mortar rubble to keep the whole open and porous. Dry bulbs, which can be purchased at this time, should be potted up as directed. After pitting, water at the root should be very sparingly given until a quantity of new roots and some growth is made; this precaution should be observed with all similar bulbous plants, as overwatering after repotting is a common cause of failure. Stock that does not require repotting should receive a good soaking at the root, gradually increasing the supply as growth develops. Nerines should not be neglected after flowering, as this is their growing period and their successful flowering the following season depends very largely on careful cultivation during that time. Not every cultivator is successful with Nerines, but they are so beautiful that they are worth some extra trouble.

Vallota purpurea, of which there are several varieties, is another bulbous South African plant, which one seldom sees in good condition in gardens. The best specimens are generally seen in cottage windows. This plant when well established and in good condition should be left severely alone, as it resents frequent disturbance. Anyone wishing to make a start with this plant can generally purchase dry bulbs about this time. As in the case with most bulbous plants, water should be very carefully given until a quantity of new roots is made. Vallota, unlike many other bulbous plants, is really evergreen, and should never be dried off altogether, although after growth is completed, the plants may be kept somewhat drier for a time.

Primulas. The main batch of Chinese varieties should now be ready for their flowering pots, 48-sized pots being usually large enough for this purpose. They enjoy a light rich compost, to which some old mortar rubble should be added. They should be potted well down, or else they become loose at the neck and tumble over. If this is done they will not rot off, as is generally supposed, but will develop fresh roots from the stem.

Primula malacoides. The most forward batch should now be put in their flowering pots. This Primula is excellent for decorative work, as perfect examples can be grown in quite small pots. On the other hand, fine groups for conservatory decoration can be obtained by placing several plants together in shallow pans.

Hippeastrums.—The earlier batches should have now completed their growth and may be removed from the growing house to cold frames, where water should be gradually withheld. The frame lights should be kept on and the bulbs fully exposed to the sun. Young stock should be kept growing steadily on, without drying off, until the flowering size is reached. Plants raised from seed sown this season should now be ready for placing in small pots, or they may be pricked off into boxes until they are a little larger. They may be grown on in pots or planted out in beds with some bottom-heat at command.

Lilium candidum grown in pots is very useful for the embellishment of the conservatory. Bulbs should be potted during August or the beginning of September. Early potting is essential to ensure success, and this Lily should be grown perfectly cool. Some lime or old mortar rubble should be added to the potting compost, as this Lily is a lime-lover. It is not a stem-rooting species, so it is not necessary to leave room in the pots for top-dressing. After potting, the pots may be plunged to the rim in ashes at the bottom of a wall.

Cinerarias for early flowering should now be in their flowering pots, while later sowings that were pricked off into pans or boxes should now be put into small pots. They should then be stood in low pits or cold frames, keeping them fairly close for a few days until they get a hold of the fresh compost. The plants should afterwards be kept perfectly cool and be given plenty of air on all favourable occasions. They should also be given plenty of room, for they soon spoil if at all crowded. When the pots are well filled with roots the plants enjoy plenty of feeding with diluted liquid manure and soot water. Fumigate lightly and frequently to prevent attacks by aphids, to which Cinerarias are very subject.

Royal Botanic Gardens, Kew. J. COURTS.

Trial of Pinks and Allied Plants.—The Royal Horticultural Society will carry out a trial of varieties of Pinks and allied plants for cultivation outdoors in their gardens at Wisley during the coming year. Three plants of each should be sent so as to reach The Director, R.H.S. Gardens, Wisley, Ripley, Surrey (Station Horsley, Southern Railway), on or before September 30. The necessary entry forms may be obtained on application to the Director.

The Foremarke Cup, for twenty spikes of named Gladioli, in not less than ten varieties and not more than two spikes of any one variety, will be offered for award at the Royal Horticultural Society's Meeting on September 4. The winner will be required to sign a guarantee that all the flowers exhibited were grown by himself. Entries must reach the Secretary, Royal Horticultural Society, Vincent Square, London, S.W.1, not later than August 29, and the flowers must be arranged by 11 a.m. on September 4.

FORTHCOMING EVENTS.

August 25.—Hawick Horticultural Society's Exhibition.—Langholm Horticultural Society's Exhibition.—Dumfries Horticultural Society's Exhibition.

August 29.—Mitcham, Tooting and District Horticultural Society's Meeting.—Sandy Horticultural Society's Exhibition.

August 30.—Royal Oxfordshire Horticultural Society's Exhibition.

SPECIAL OFFER OF NEW AND CHOICE NARCISSI

"BRITAIN'S BEST BULBS." ORDER NOW—BRITISH GROWN BULBS.

Don't put off your planting much longer, or the results will not be nearly so good. We have just harvested the best bulbs we ever saw, and nearly every order brings a testimonial. Two seasons ago we sent a customer in New Zealand some bulbs. He ordered more this time and says: "Your bulbs are the best I ever had. Tenedos gave me two fine blooms first season, and this time is throwing up ten strong noses." Exhibitors who want really fine bulbs should place an order at once.

Ace of Diamonds (Poeticus) This is, undoubtedly, the finest all-red eyed Poeticus yet seen. Most perfectly formed, well overlapping perianth of splendid substance, wonderful quality, smooth texture and purest white, while the eye is intense solid, blazing hot orange-scarlet throughout. Each, 50 -.

CRÆSUS (Incomparabilis). This famous flower is still the finest richly coloured Incomparabilis and, being of vigorous and free increase, is now listed at, comparatively, a very moderate price. Each, 7 6.

CRYSTAL. A very fine and distinct Giant Leedsii, having symmetrical, flat, overlapping, pointed, pure white perianth, and bold, clear lemon crown of almost equal length with the segments. A fine show bloom, the flower has great substance and lasts a long time in good condition. Each, 1 6; per dozen, 15 -.

Donax (Incomparabilis). One of the late Mrs. Backhouse's remarkable introductions. A most distinct and striking flower, having a broad yellow perianth and wide orange-scarlet cup; a variety that is bound to become popular and worthy of a place in the very best collections. One of the three varieties that carried off the "Walter Ware" Challenge Cup at Birmingham, 1921. Each, 6 6.

DRAGON. Undoubtedly, one of the most brilliantly coloured Narcissi extant. Flower as large as Albatross, with fine, spreading, white perianth of good substance, and large, shallow, spreading crown of clear, bright vermilion; very striking. A tall and robust plant. To get the colour at its best the flower should be cut young. Each, 10 6.

Everest (White Trumpet). The flower is pure white throughout and is of fine waxy texture, having broad, well formed perianth, standing at right angles to the trumpet, which is beautifully finished with a neat flange at the brim; perhaps its most striking feature is its tallness, having a stem quite 20ins. long. A wonderful show flower. Award of Merit, 1922. Each, £4.

GOG (Yellow Trumpet). A very early and very vigorous Yellow Trumpet; a fine long stem, carried very erect; bound to become a popular variety, as the constitution is the best we have seen in any yellow Trumpet; altogether a pleasing variety. Each, 7 6.

ILIAD (Poeticus). Raised by Mr. Engleheart, and, although chosen from a great collection, we feel we have got one of the very best. It has large, smooth, broadly overlapping, circular, snow-white perianth of exceptional substance, without undue thickness, and perfectly formed, flat, citron eye, cool green in the centre, and neatly rimmed bright red; quite perfect in balance, and of exquisite refinement, and difficult to conceive a more beautiful flower; bound to become popular. Each, 5 -.

Irish Pearl. One of the very best Giant Leedsii's ever raised from Minnie Hume, crossed with a Trumpet; large flower, having splendid overlapping white perianth of great substance, and large, bold, beautifully frilled crown, opening primrose, soon passing to white. The plant increases with great rapidity, and is exceedingly vigorous and free blooming. Each, 3 6.

Kingcup (Incomparabilis). A big, self, clear yellow flower, having broad perianth and shallow crown; best described as a glorified Homespun. Each, 2 6.

Lemon Star (Giant Leedsii). One of the best of its class. A large flower with overlapping and pointed white

perianth and large, pale lemon crown; a tall and vigorous plant; a good seeder and pollen parent. Each, 3 -.

MAGOG. A splendid, graceful, self-golden giant Trumpet of immense stature and vigour; stems like walking-sticks and great foliage. Somewhat after King Alfred in style, but larger. Will grow where King Alfred fails. A.M., 1922. Each, 5 -.

PROSPECTOR (Yellow Trumpet). Mr. Engleheart has described this as the deepest yellow Trumpet known to him and, when shown in London in 1921, it stood out in marked contrast to any other variety on the stand; it demanded attention and, look where one would, one's eye always seemed to rest on that one variety. A pure dark golden self, the flower has twisted perianth and a neat flange at the mouth of the trumpet. Very lasting, either on the plant or when cut. Each, 10 -.

Quicksilver (Giant Leedsii). A charming, dainty and very early variety that passes to pure white very soon after opening; a very rapid grower and most profuse bearer. Each, 2 6.

SELINA MALONE. Certainly one of the finest Bicolor Trumpets yet offered. Flowers of enormous size, yet of beautiful quality, having grand, broad, smooth, white segments and noble, clear soft lemon trumpet; grows with great vigour; a thoroughly satisfactory flower. Each, 10 6.

Silver Fox. A very large and striking Giant Leedsii, with spreading white perianth and large, well expanded crown, which is more or less reflexed at the brim; the crown opens sulphur, but very soon the whole flower passes to pure white. Very tall and vigorous; a fine effective garden plant. Each, 7 -.

Siskin. A very nice flower of the flat-eyed type; spreading, even, pale primrose or ivory-white perianth, and richly coloured expanded eye. Comes very good under glass. Each, 1 6.

Sonata (Poeticus). A late-flowering variety of much refinement; beautiful perianth of fine substance and flat, cool citron eye, with a very narrow rim of dark crimson. Each, 1 6.

THETIS. A grand Poeticus; great round flowers having broad, rounded, well overlapping snow-white segments of much substance, and large, rich, red eye. This can be highly recommended as a garden plant, and keeps its colour better than many of the older Poeticus. Each, 2 6.

WHITE EMPEROR (White Trumpet). From the standpoint of the florist and exhibitor alike, this superb flower is unrivalled. It has attained in the marble-like smoothness and solidity of its texture, and classical purity, and perfect symmetry of its outline, a point of excellence beyond which it is difficult to imagine much improvement. For many years it will be indispensable to all who aspire to the front rank as exhibitors, and to the hybridist it will be no less essential; it is a very free seeder, and produces abundant pollen. It is now reaching a point in price where the Daffodil expert considers it modest, and indeed it is, compared to the price a decade ago. Clean, healthy bulbs. Each, £3.

White Star (Barrii). A distinct and very beautiful flower of decorative type, spreading star-shaped pure white perianth of good substance, 4ins. in diameter; shallow crinkled crown of a beautiful, cool, greenish primrose. A very charming and refined flower; plant of good constitution. Each, 5 -.

**THE PRIMULAS
OF EUROPE**

With Botanical Classification, Descriptions, and
Cultural Instructions

By **JOHN MACWATT, M.B.**

Crown 8vo., Cloth, 12/6 net; Postage 9d. extra.

The aim of the author has been to produce a handbook that will assist in the identification of those species of the genus *Primula* which are native to the European continent, and at the same time furnish practical guidance to the cultivation of such of them as have been introduced to our gardens where conditions differ so widely from those prevailing in their natural habitats.

Dr. MACWATT is an acknowledged authority on Primulas, and his book presents in a concise and interesting manner the results of many years of close personal observation and experience.

The World is made of—

ONE big reason why Kit is indispensable to gardeners is that the world is made of dirt. Kit, the rapid action hand-soap, can dig out of the pores of the hand any dirt that can get ground into them. Ordinary dirt it laughs at; paint and tar it can shift with ease; oil and grease it can banish at the first rub.

You'll notice that Kit leaves the hands feeling clean, as well as looking clean; that's because Kit has worked deeper than ordinary soaps can.

A CONVINCING TESTIMONIAL.

"I am very pleased with the Greenhouse. I have had great pleasure in showing friends the new house. No doubt you will have to supply others before long. I shall always be pleased to show any enquirers the house and can, with the greatest confidence, recommend your firm for good-class work and attention. I may require others later, and will send direct to you."

"I am now awfully disappointed with my other houses I had a few years ago from various other firms. I cannot now admire them after seeing yours erected."

Can be erected by a youth in 90 minutes or less.

Can be taken down in same time when required without removing a single pane of glass.

Prices are often misleading. Only careful scrutiny of the specification can assure you of sound value for money.

CAMPING.—All Campers and lovers of out-door life should read "Camping," by J. SCOTT MOORE, published at the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, W.C.2; price 9d. net; by post, 11d.

TOMATO CULTIVATION: UNDER GLASS AND OUTDOORS. By R. CHILARD WOOLLEY. A practical booklet by the Editor of "THE GARDEN," 9d. net, by post 11d. Published at the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

SPECIAL OFFER OF NEW AND CHOICE NARCISSI

"BRITAIN'S BEST BULBS."
ORDER NOW—BRITISH GROWN BULBS.

Don't put off your planting much longer, or the results will not be nearly so good. We have just harvested the best bulbs we ever saw, and nearly every order brings a testimonial. Two seasons ago we sent a customer in New Zealand some bulbs. He ordered more this time and says: "Your bulbs are the best I ever had. Tenedos gave me two fine blooms first season, and this time is throwing up ten strong noses." Exhibitors who want really fine flowers should place an order at once.

Almagra	40 - each.	Lady Margaret Boscawen 9 - doz.,	10d. each.
Alpine Snow	4 - each.	Leontes	6 - each.
Aspasia	3 - doz.	Loch Fyne	4 - each.
Athos	1 6 each.	Lord Kitchener	1 6 each.
BERNARDINO	2 - each.	Lord Roberts	1 - each.

THE HARDY CYCLAMENS

BELONGING to the Primula family, the genus *Cyclamen* consists of about twelve species, limited to Central and Southern Europe, North Africa and Asia Minor. All the species are great favourites, with lovely flowers, some very fragrant and produced in profusion over a long period. In addition, the foliage of several kinds is very elegant and ornamental. The hardy members are of the greatest value for planting on rockwork, in the wild garden under trees and in shady places where few other plants will thrive. The culture of hardy *Cyclamens* is quite easy, although they flourish more freely in the southern and warmer parts of the country. In their native habitats they are found on rocky sloping banks, generally under the shade of trees, with a northern aspect, in chalky, stony, porous soil, out of reach of any stagnant moisture. Here the tubers are wholly or partially above ground, among moss, low-growing herbs and buried in dry leaves in winter, which act as a protection against frost. In this country it would hardly be possible to grow them in this way, but success may be attained by carrying out the following directions.

When planting select a perfectly drained border or sloping bank of porous soil; if of a heavy nature, add plenty of sand, well decomposed leaf-soil and pieces of old mortar rubble. Plant the tubers when they are at rest, from June to August for autumn-flowering species, and from July to November for spring-flowering ones. Surround the tubers with sand and take care that the tops of the tubers are level with the ground. If the soil is dry give it a good soaking, afterwards applying a layer of sand, leaf-soil, coco-fibre, moss or any similar material, and see that the soil does not get frozen during the winter. The fern border is an ideal place for *Cyclamens*. They there get shade and suitable conditions among the matted roots. *Cyclamens* may be propagated by cutting the tubers

into pieces, leaving one eye attached to each division, or by cuttings of leaves having a small portion of the tuber attached to the base of the leaf-stalk. The best way, however, is by means of seeds, which are freely produced. When fresh they germinate in a week or two, but when old they are much longer in coming up, sometimes lying dormant for a year or more. Sow the seeds as soon as ripe in pans or boxes of light, sandy soil, keep moist and shaded till the seedlings are up. Winter in a cold frame for the first year and the following autumn, when the small tubers are at rest,

replant them rim or rim, apart in a similar compost. The following autumn they will be ready for planting out and will flower in the second or third year from seed. In the south-western parts of this country they may be naturalised and will spread quickly by means of self-sown seedlings. Of the following some are autumn-flowering, others bloom in spring, while *C. europæum* flowers in summer.

C. AFRICANUM.—A native of North Africa, where it grows in sandy oak woods; this is less hardy than the others. It is closely allied to *C. neapolitanum*, with large tubers and ornamental marbled leaves. The flowers are sweet scented, pale or deep rose in colour, with a purple spot at the base of each petal, and are produced in October and November.

C. ATKINSONII is a hybrid between *C. Coum* and *C. ibericum*, nearer to the latter, but with slightly larger foliage. The flowers vary in colour from purple and rose to white. It is a valuable plant for spring flowering, for besides being quite hardy in the border, it is suitable for growing in pans for display in the alpine house.

C. CILICICUM.—An autumn-flowering species from the mountains of Cilicia and Asia Minor, where it grows in fir forests; this is closely allied to *C. europæum*, from which it differs by its pulverulent calyx and other small details. The leaves are entire or slightly serrate, purple beneath, appearing with the flowers. The blossoms are pale rose or pure white and strongly scented.

C. COUM.—This beautiful little early spring-flowering species comes from the mountains of the Caucasus, Asia Minor and Greece. It is very distinct, with small corms and round, dark green leaves that are never marbled, and deep purple beneath. Appearing with the leaves, the flowers are small, deep purple or rose, and are produced from January to March. There are several varieties in cultivation, including a white-flowered one.

CYCLAMEN NEAPOLITANUM, FLOWERS FROM THE LEAFLESS CORMS.
The illustration shows the white-flowered form.

THE SPRING-FLOWERING *C. REPANDUM ALBUM*.*CYCLAMEN COUM* HAS FOLIAGE DESTITUTE OF MARBLING.THE VERY HANDSOME RICH ROSE-COLOURED *C. PSEUD-IBERICUM*.

It is one of the hardest kinds in the family, easily grown and valuable for the alpine house. A plant known as *C. calpinum*, from Mount Taurus, is only a form of this, with leaves faintly marbled and pink flowers.

C. CYPRICUM.—As its name implies, this is a native of Cyprus, and is closely allied to *C. neapolitanum*, differing chiefly in its unfolded leaves and longer, narrower petals. It bears white flowers, each segment having a purple spot at the base. This is a plant rarely met with in gardens.

C. EUROPEUM (Snowbread).—Also known as *C. odoratum* among a host of other synonyms, this species is widely distributed in the mountainous regions of Central Europe, Greece, Asia Minor and the Caucasus. It is of easy culture, with deep green leaves that are rounded with a cordate base, usually entire, marbled with white above and purple beneath. The flowers are purplish-red, darker at the base, strongly fragrant and produced from July till October. It is one of the best for the shady fern border or bank and has almost evergreen foliage. For this species calcareous soil is preferable.

C. HEDERICUM (syn. *C. vernum*).—This comes from the Iberian Caucasus and may be considered a form of *C. Coum*, with marbled leaves and larger flowers, varying in colour from purple to deep rose and white. It flowers rather later than *C. Coum* and the petals are sometimes blotched at the base. It is a charming spring-flowering plant, quite hardy and easy to grow, either as a pot plant or in the border.

C. LEBANOTICUM comes from the valleys of the Lebanon, at an elevation of 2,000ft. to 4,500ft., where it grows in rocky ground of a chalky nature. The leaves are large, with entire margins and are marked with a silver zone on the upper surface, while the underside is dark violet. The flowers are large, sweet-scented, bright pale rose in colour, with a carmine blotch at the base of the petals. It flowers in February and March and is hardy in sheltered positions.

C. NEAPOLITANUM (syn. *C. hederifolium*).—This beautiful autumn-flowering species is one of the best and most useful plants in the genus, being quite hardy. In the autumn it produces its flowers in abundance, followed by beautiful marbled leaves, which persist through the winter and following spring. It is a native of Southern Europe, but does not extend into Asia Minor. In old plants the tubers get very large, often one, or more in diameter. The leaves are variable, elegantly marked with white above and purplish beneath. The flowers are of good size, rose coloured in the type, but there are many varieties, some pure white. The blossoms are produced from August to October.

C. PSEUD-IBERICUM.—This is one of the finest of the *Coum* section, but of doubtful origin, being described from plants growing in the nursery of Mjühr, Van Tubergen. The leaves, like those of *C. ibericum*, are marbled with a zone of white, but instead of being entire the margin is crenulate and the underside of a richly-purple colour. The rich, rose-coloured flowers are borne well above the foliage in March.

C. REPANDUM.—This spring-flowering *Cyclamen* is often erroneously called *C. hederifolium*, a name which is also often used for *C. neapolitanum*. It is a native of Southern Europe, being plentiful in Central Italy, and ascending to 6,000ft. on the Greek mountains. The tubers are small and produce tufts of toothed, angular leaves, beautifully marbled with white above and purplish beneath. From March to May the flowers appear with the leaves; they are rosy white and spotted with purple at the base of each petal and larger than those of *C. europæum*. This species on the whole

is rather more tender than the others and requires a more sheltered position. It is also known as *C. bicaristifolium* and *C. vernum*, the latter name also being applied to *C. Comm.*

There are some other species which have been omitted owing to their being less hardy and rarely

grown in gardens, such as *C. balearicum*, a small species from the Balearic Isles, with marbled foliage and pale lilac flowers; *C. gracum*, and *C. latifolium*. Both the latter are found in Greece, are closely allied and do not stand our winters well outside.

W. L.

LILIES IN THE GARDEN

(Concluded from page 441.)

LAST week I mentioned *Lilium Hanson* as among those that were indifferent to the presence of lime in the soil, but, although this is of Japanese origin, it must not be concluded that all the beautiful Lilies of Japan tolerate lime. On the contrary, the majority strongly object to it. Of most of the Japanese Lilies it can truly be said that where Rhododendrons, Azaleas and the lime-hating shrubs generally, do well, the Lilies will thrive.

Among the finest of those that come from the "Happy Isles of the East," are the auratum, followed closely by the Tiger Lilies and the various forms of speciosum, or as it was at one time better known, lancifolium. The best of the auratum is, undoubtedly, platyphyllum, not only on account of its magnificent size, the glorious breadth and rich green of its foliage, but because it is by far the most vigorous and easiest to grow and the one that establishes itself more satisfactorily than any other in the English garden. It was my good fortune, a few hours after posting the previous instalment of this serial to the office of THE GARDEN, to stumble across a planting of this wonderful Lily in a garden less than twenty miles from Charing Cross. The accompanying photograph is of one of the clumps, selected rather on account of its more even lighting for photographic purposes than because it was the best. There is, indeed, a gardening lesson in this uneven lighting (for photographic purposes) of the remainder. Mr. Brown, the gardener at Castle Hill, had skilfully chosen spots where the Lilies, planted in the shrubbery, would be partially shaded during the brightest period of the day. The planting was also arranged so that the foliage of the shrubs surrounding the masses cast a shadow over the roots of the Lilies, which undoubtedly in large measure accounts for his success. Incidentally, I saw also in the same garden, planted in the borders, several clumps of the wonderful *L. Henryi*, planted about four years ago, towering above the taller herbaceous plants and full of health and vigour, just opening their first flowers. This, the wonderful "orange speciosum," is really a deep apricot in colour. It is a Lily that should be planted wherever any of them are being used.

In the same garden, old established masses of *L. pardalinum* had gone off for this season, but had left enough to shew how truly magnificent they had been. But to return to the auratum; although platyphyllum is essentially the variety for the novice to obtain, having grown it he will not be content to possess this variety alone. Sooner or later he will come across the gorgeous red-banded rubro-vittatum. The enormous richly fragrant flowers of this variety are among the most startling productions of the Japanese flora in England. The blossom has six huge white petals, each with a bright crimson band down the centre or mid rib. It is a little variable in colour intensity and there are, undoubtedly, some forms better than others, but all are striking and, moreover, all are good garden plants. I remember seeing in a Suffolk garden some years ago groups of these two varieties growing in a large bed of Rhododendrons. The Lilies had been there twelve years and many stems were 5ft. to 7ft. high, carrying over twenty fine

blossoms. A third variety that can be added is Wittei, when obtainable. It is the whitest of all the auratum, being quite devoid of spots. All, of course, are very fragrant.

A FOUR-YEAR-PLANTED BULB OF LILIUM AURATUM PLATYPHYLLUM IN A GARDEN NEAR LONDON.

The Tiger Lilies are a very important group because of their late flowering and also on account of their wonderful orange colours. The best of them is *L. tigrinum Fortunei giganteum*. Thirty flowers of the deepest orange, richly spotted, on a spike 6ft. or even more high is a common occurrence. In some parts of the country this Lily does not flower until late August or September; of course,

seasons and local conditions vary this period somewhat, but it is essentially among the late Lilies. By this time the foliage of Azaleas has begun to change to brown and bronze tints, and if the Lily-grower wants to see this gorgeous variety at its best he will plant it in groups among Japanese Maples and Azaleas. Remember, when choosing its position, that it grows anything from 5ft. to 7ft. high.

The earliest of the Tigers is splendens, flowering in late July and August. The type tigrinum (or sinensis) is perhaps a little later, and there is a double form called flore pleno that rarely flowers before the other two are well out. The average height of these is 4ft., but splendens will exceed it under good conditions.

Among the later flowering Japanese Lilies none is more beautiful than the speciosum group. From pure white to the deepest crimson, all the varieties are good. The pure white form album Kratzeri, is one of the most wonderful white flowers in the garden. Not the purest white, perhaps, although its green central band detracts nothing from its exquisite beauty and, indeed, emphasises the purity of the remainder of the sepal, but it is the best white for outdoor culture. Of the rose and red forms there are several varieties of which roseum superbum, Melpomene and magnificum are the best investment for the average gardener.

Where shall I stop? There are enough Japanese Lilies left really demanding all the space available for this, the last of the present series of articles. I must, however, just mention a few other good sorts by name and then leave the reader to make enquiries for any further information required about them. For the borders there are the charming and mostly dwarf early-flowering Thunbergianum (or elegans) section. Orange Queen, venustum macranthum and Van Houttei are a representative trio of the best. Late May and June is the flowering period and none of the section grows more than about 2ft. high, some of them hardly exceeding 6ins. A little later than

these follow the unbellatum (davuricum) section, of which the pure orange yellow form known as davuricum luteum is by far the most attractive, although grandiflorum, incomparabile and Sappho should also be planted. June and early July is the flowering period; colours yellow, orange and crimson, but mostly orange. Everyone who has a peaty soil and a bit of thin

odorous, but of a pleasant, so-called, "Krameri" (so known, and more correctly "Lapponicum"), but it can be grown in any good light soil, well drained. In some cases it is the most delicately fascinating of all the pink Lilies. A species that resembles it, *abellum*, is perhaps of better and more vigorous constitution and in favourable circumstances has been known to seed itself about. Frankly, however, I think it inferior in colour and form to *Krameri*, but it is really well worth growing.

On the *L. longiflorum* group I do not intend to waste much space. Perhaps of all the Lilies of Japan they are the best known, because of the popularity of their pure white trumpets, as florists' flowers. They can be grown out of doors, but are really much better as pot plants under cover, and few people have been able to get them to perpetuate themselves in the open. If they are required for outdoors, and no one can deny that they are very useful there, then it is best to procure sound new bulbs each year and plant afresh.

Now, I must leave the Japanese Lilies, although the tale is not yet half told, and just mention one or two of the Chinese forms. Before doing so, however, I must notice the noble Himalayan

would be too fantastic, no language too high flown, or extravagant to lavish on the wonderful species of the genus that have reached us from the little known regions of Central and Western China. As it is I must be content with a "practical" reference to one or two kinds that readers of *THE GARDEN* can plant out of doors, and first and foremost comes *L. regale*, queen of the tribe. Hardy as any species in cultivation, it grows and flowers and seeds so freely that it is getting more and more popular every year. In America it has been grown by the acre for cut flowers. In England I venture to say that had there been no Great War there would have been millions where there are now thousands. Nothing among Lilies can exceed the beauty of its exquisitely shaped flowers. These are borne on sturdy stems furnished from the base upwards, thickly, with long narrow leaves, and are funnel-shaped, white, suffused with yellow on the inside and pale pink outside, the pink deepening towards the mid rib where it becomes a ruddy brown. The pink seen through the white gives to the flowers a pearly texture that is exceedingly attractive. Newly planted bulbs produce anything from two to six flowers according to the condition and age of the bulb, but established bulbs often bear many

There appears, however, to be no reason why it should not succeed.

I must also point out that the collection I have named is quite incomplete, but I think it is large enough to meet all the requirements of the gardener who wants to try to grow Lilies in his or her own garden for the first time. As enthusiasm grows the list can be extended and it will be, because the enthusiasm will grow.

The new grower of Lilies will be too impatient for results to wait for the produce of seeds. Nevertheless, increase of stocks can be quite easily achieved by this method and seeds of most varieties can be obtained. The directions need be but brief. Sow on gritty soil in shallow pans that are thoroughly drained, just covering the seed with sand. Plunge the pans in ashes or some material that will ensure that the soil never gets dry, and also reduces the necessity of frequent watering. The seeds will come up rather irregularly, that will be the more pronounced the longer they are kept after they are ripe before sowing. Even if some of them fail to put in appearance during the first year, do not give up hope. If the seeds are sound, that is if you can find them in the soil, they will come up in time. The first year's growth will look about as unlike what you expect a Lily should be as possible, but little bulbs will be formed which can be pricked off in pans or a frame, after the first leaf has died down. As these little bulbs will be in very shallow soil the protection of a cold frame or even a cool greenhouse is desirable. When the bulbs are large enough they can be transplanted to permanent quarters or into nursery lines to be grown on until they flower. Some sorts, such as *regale*, can be sown in cold frames and left for two years, when they can be transplanted into nursery beds and the largest bulbs selected from time to time for planting as required. Some varieties will take much longer to flower than others, the quickest results I have known being with *L. philippinense* (Price's var.), which flowered sixteen months after sowing. Some sorts may take as long as four or five years to flower. Whether it is worth while is a matter for the individual to decide, but there is certainly an added interest in raising one's own seedlings and watching them mature; moreover, the survivors are acclimatised.

In concluding this article it may be as well to raise the question whether the Lilies themselves are worth the trouble. After all, what does this trouble amount to? There are hundreds of things you grow in the garden that require as much or more, that do not possess one half the individual attraction of well grown Lilies. Compare them with many other flowers in the garden and it is Lilies first and all the time. Apply the test, an analytical test, by quoting a well known writer on matters of art and beauty. "The first necessity of beauty of line is curvature." No plant in the garden possesses more exquisitely curved lines than the Lily. Every line is moulded to delightfully varying curves. "Of colour gradation"—the softly graduated colouring of many of the Lilies is unequalled in all the world of floral colour. "The second necessity of colour is subtlety." Try to state in definite terms the true and exact colour of such Lilies as *Krameri*, or *regale*, and you will realise what a difficult problem subtlety of colour can be. "And the second necessity of line is softness." It is just that softness of curved lines that has caused the Lily to be held up through all the ages as the perfect flower and a symbol of all that is beautiful, and also that has caused so many flowers that have no relation to the genus to be called some sort of "Lily." Not all the art of all the painters, nor all the fancies of all the poets throughout the ages, could achieve the impossible and "paint the Lily" in nobler sublimity than that of which it is worthy.

GEO. DILLISTONE.

LILIUM REGALE AMONG RHODODENDRONS.

L. giganteum. Plant young bulbs of this in the rich leafy deposit and half shade of woodland, or as near as it is possible to get to such conditions. See that the position is one in which they will never get dry and they will attain the noble stature of rosette, or so and bear large spikes of their long tubular white flowers, above luxuriant and enormous bright green leaves. A really fine group of this Lily is a sight never to be forgotten. If you plant large bulbs you may succeed in getting them to flower the first year, but they may die before they attain maturity. If you plant smaller bulbs they may not flower the first year, but will establish themselves much better and are certain to succeed if the conditions are suitable.

Chinese Lilies. If I were a real journalist instead of a very hard worked garden-maker, I should revel in just this one theme. No poetic flight

more flowers on a stem. This is *par excellence* the Lily for the garden. Another Chinese Lily that is equally satisfactory, although of quite a different type, is *pseudo-tigrinum*. Deep orange flowers, an orange that has much more red than yellow in it, August-flowering, often lasting well into September, tall, slender and therefore graceful, it bears numerous reflexed flowers, in a nodding position, above the dainty narrow leaves which almost cover the stem from the base upwards. It has a constitution that makes it doubly valuable for the garden.

Of the other Chinese Lilies I can say little now. Some of them are for the garden, a few are better grown indoors. *L. Willmottiae* has been grown successfully out of doors, but it is too new and untried for the novice to risk just yet. Only the expert, too, will feel inclined to risk *centifolium* until it gets more plentiful and, therefore, cheaper.

THE BULB ORDER

V.—Tulips.

I HAD a mild shock last week. A contemporary gardening paper announced the result of its readers' selection of the twelve most popular garden flowers of the present day and the Tulip was not one of those in the list. I would not have thought it. This venerable inhabitant of gardens has had ups and downs in its long career, but I imagined that after the reaction of the show period about the latter part of the first half of last century, it was rapidly regaining its lost position, if it had not already done so. The space given to Tulips in any decent-sized modern bulb catalogue is very striking, and I cannot think why it is so large if it is not an index of the flower's popularity. If Petrus Hondius in his "*Dapes Inemptæ*" (1610 and 1621) correctly represents the garden feeling of his time, the Tulip must have enjoyed a prominence which it might not be too much to call the high-water mark of its appreciation. He calls it

"An Emperor flower extolled
Over every flower being."

Later on in the poem he says some people were so much taken with its beauty that they gave up the cultivation of all else. He calls them foolish "Who build their gardens for one flower and no other."

Clearly, in the days of Petrus Hondius the Tulip had caught on and had become a very fashionable flower. Has it ever had a greater vogue than it had then? This it must be remembered was fifteen years before the mania (1635-37), when, presumably, it was grown for pleasure and not for profit. Our ideas have changed. Few, if any, give themselves up to-day to the cultivation of one flower only. People want a succession in order to have their gardens bright for as long a period as possible. No flowers can provide brighter colours in April and May than Tulips, hence their popularity in modern times. In the early sixties of last century, when Cliveden was looked up to as the ideal spring garden and when none could rival Dropmore in bulb-gardening, it was the early varieties, as we now call them, that were used in their displays. It was a variety like Yellow Prince, Vermillon Brilliant or some Duc van Thol that would come to mind if anyone then said "Tulips," just as the modern man when he hears that word thinks of the taller and more important looking May-flowerers. I will deal with these first. Everyone who orders Tulips, orders some of these, but the "Mau in the Street" is bewildered as he takes up his catalogue to make out his order. Not only is the assortment large, but the descriptions are perplexing. Some of the cheap Dutch catalogues take the cake. I have seen one in which The International and Ronald Gunn are both described by the one word "violet," whereas the former is a rich ruby red and the latter a greyish mauve or lilac.

It is very difficult to convey the small differences in very-much-alike varieties in black and white, but that is no excuse for making two Tulips which are as different as a spaniel from a foxhound, seemingly identical. If I tried to please everyone I should most likely please no one. I am not quite sure that I can select a dozen Darwins, or a dozen Cottage and Breeders that will please myself, but the selections which follow are at least an honest attempt to do so. My dozen Darwins are: Clara Butt (pink), Eclipse (deep mahogany red), Edmée (rose, edged bluish), Euterpe (long soft lilac-mauve), Faust (deep reddish-purple), Marconi (dark violet-purple), Petrus Hondius (bright rose), Pride of Haarlem (cerise), Prince of the Netherlands

(deep cherry-red, edged soft rose), Ronald Gunn (greyish lilac and purple), Sophrosyne (delightful soft rosy pink), and Teddy (a very bright scarlet). It made into a baker's dozen the thirteenth would be Crêpuscule (round silvery blue). Afterglow is

PARROT TULIP FANTASY, SAID TO BE A SPORT FROM THE WELL KNOWN "DARWIN"
CLARA BUTT.

left out because we get orange reds in the Breeders. The pure white Zwanenburg is at present for millionaires only. Mrs. Maurice Tweedie, an idealised Crêpuscule, has not as yet left Whitewell. Miranda, which came from Holland originally, I can no longer find in any list. It is an improved International and supreme in its shade of colour. Elephant, the huge slaty-grey, is a wonder when seen at the top of its form, but it does not seem quite as robust as it might be. William Pitt, the deep blood red, is only turned down with tears. Venus, the tall soft rose, begged hard to be one of the lucky thirteen. The great big dark purple Giant ought to be with the elect. How could I fail to select Homer, La Fiancée, Duchess of Hohenburg, Jubilee, Yolande, Farncombe Sanders, Moralis and Professor Francis Darwin? Practically, what does all this mean? It means there are many excellent varieties—one quite as good as another. It is fortunate it is so, for it takes a great many to go round now that everybody with any sort of a garden wants some. It is not so difficult with the Cottage and Breeders, which I find are put into one section in most English lists. A favourite twelve of mine are the following: Avis Kennicott (long deep yellow), Boadicea (orange red and brown), Bronze Queen (biscuit colour), Ellen Willmott (primrose), Gesneriana major (deep scarlet), Golden Crown (yellow, edged rosy red), Louis XIV (purple and bronze), Lucifer (orange red), La Merveille (long flower, orange-carmine), Marksman (magnificent scarlet), Picotee (white, edged rose), and Prince Albert (rich brownish-yellow). To make a baker's dozen Inglescombe Pink (many

pink) must be added. Perhaps the thirteenth should have been Orange King (orange) or Mrs. Kerrell (the lovely pink), or The Fawn (fawn and white). It is a difficult matter to say which. For growing for cutting, either outside or in a cool house, few Tulips in my estimation are before the fascinating light bizarre Zany. There is a peculiar charm in the straw-yellow ground colour, flaked and edged with a pretty shade of carmine, and when the flowers are associated with a pale bright-toned

green it is a "bit of all right." Are rectified (or striped) Tulips coming into fashion again? The firm of Dobbie and Co. is shrewd and far seeing. In their 1922 bulb list they honoured me by quoting my opinion about a bed of Rembrandt Tulips, which I have called a "bewildering medley of colour." It is. But a bed of rectified *pure bred* English Tulips, when at its best, is something brighter and more glorious, because the colours are purer and the bases either pure white or pure yellow. What would I not give for a peep into the past to see those famous Tulip beds of Groom, the great florist, which yearly attracted all fashionable London? We have plenty of better varieties now and the mixture of "Old English Tulips" which this firm lists contains many of them.

If asked to name a good half dozen early and mid-season varieties for growing in the garden in clumps, I should name the following: Cramoisie Royale (cerise), Canary Queen (primrose, edged lemon), Prince of Austria (orange-red), Prince de Ligny (yellow), White Swan (white), and Thomas Moore (terra-cotta with buff edge). These are all tall growers for early varieties. With the mention of Fantasy I must bring these notes to a close. It is, I believe, nothing but the well known Darwin variety Clara Butt, which has sported and taken on a "parrot" form. The colour is a soft rosy pink, with here and there green splashes running through it. I have not grown it myself, but I have seen it at shows and was greatly struck by it. It is, unfortunately, rather dear to buy as yet.

JOSEPH JACOB.

GLADIOLI AND DAHLIAS AT VINCENT SQUARE

So far as exhibit at the Royal Horticultural Hall, Vincent Square, on August 21, were concerned, it was still practically a close season with Orchids, for there were no novelties and only a handful of plants. The Fruit and Vegetable Committee also had in easy time; but, while it was not a large show, the Floral Committee were well employed. At eleven o'clock the Joint Dahlias Committee, which is composed of members nominated by the Royal Horticultural Society and the National Dahlia Society, had to consider the merits of a large number of new Dahlias. A few of the novelties might have been relegated to the rubbish heap on sight, but, generally, the quality was decidedly good. An improvement was especially noticeable in regard to the flower stalks, which were in all cases long enough to bear the flowers clear above the foliage. Some exhibitors did not seem to realise that, for award, three blooms of a novelty must be sent. Besides these new Dahlias, there were a couple of good collections in the hall. Their size and quality encourages the National Dahlia Society to expect a good display at their annual show on September 5.

In addition to the new and rare plants described in due course, there were several well grown specimens of less common though not rare species. Mr. C. Turner sent splendidly flowered branches of *Erythrina Crista-galli* and *Clerodendron tomentosum*. Mr. N. Hadden, West Porlock, Somerset, exhibited exceptionally well flowered sprays of the tender *Lonicera Hildebrandiana*, which appeared to have been grown out of doors, probably against a

warm wall, and he also shewed the interesting *Bonania multiflora*. The Common Marjoram, *Origanum vulgare*, sent by Mr. Lawrensen, though quite a common wildling, seemed to be hitherto unknown to quite a number of visitors. This herb is very pretty when in flower.

Gladioli again filled the public eye to a great extent and there were some very pretty and uncommon colourings among them, in addition to many standard sorts. Major Churcher had a large collection and his bowls of Alice Tiplady, Sedan, Woodcote and others were prettily arranged. Montezuma was again very attractive, as also were Magic and Martha Washington. In the exhibit by Messrs. Lowe and Gibson there were several of weird and fascinating colours. John T. Pirrie and Adriatic are examples. Zanthia, a neat *Primulins* of deep orange shades was much admired, as also were Red Fire and the American St. Thomas. Messrs. Kelway and Son had a good collection of the large-flowered sorts, and Mr. Alfred Edwards of Fordham, Ely, a very bright and attractive lot of *primulins* hybrids.

The general floral exhibits chiefly included second spikes of *Delphiniums*, *Rudbeckias*, *Helianthi* and herbaceous *Phloxes*. Mr. G. Reuthe shewed *Eucryphia cordifolia* very well set with flowers. Mr. Geo. G. Whitelegg has in Schubert and Preciosa a couple of desirable garden Pinks.

A magnificent collection of *Montbretias* was exhibited by Messrs. Sutton and Sons and these were "backed" by *Phlox Drummondii* and *Verbenas* in great quantity and a variety of

beautiful colours. The *Montbretias* included Henry VIII, Queen Mary, Carmine, Una, Tangerine and other admirable sorts.

It is not an easy matter to exhibit a first-class collection of vegetables just now, but Messrs. Barr and Sons were able to make a display that filled many visitors with envy. They set out, in the best exhibition manner, practically all seasonable kinds in as near perfection of form as possible. When all the items are so good it is difficult to select any for special mention, but we are inclined to the opinion that the Tomatoes, Golden Sunrise, Scarlet Beauty and Peach, and Beet Covent Garden Compact Top, were the very best. Those who are interested in the uncommon sorts admired the perfection of the Long Purple Aubergines, the Golden Padded Butter Beans and the Large Green Paris Globe Artichokes.

A noteworthy collection of fruit was contributed by Mr. A. J. Nix, Ulghate, Crawley. The well grown bunches of Black Hambro Grapes, weighing 10lb., were stated to have been cut from two vine rods. The Peaches included Grosse, Mignonne and Bellegrabe, but even better than these was the large dish of River's Early Orange Nectarine, which was of superb quality. Messrs. Daniels Bros., shewed a large quantity of their splendid Daniel's September Black Currant.

NEW AND RARE PLANTS.

***Chimaphila maculata*.** This pretty little plant so fascinated the Floral Committee that it granted a first-class certificate straight away and with

MOST BEAUTIFUL OF THE WINTER-GREEN CLAN, THE FRAGRANT CHIMAPHILA MACULATA.

this award most would be in agreement, for it has uncommon beauty of flowers and foliage, to which is added the charm of delicious rather hawthorn-like fragrance. When young, the lanceolate, toothed, slightly fleshy leaves are of a delicate pea green colour with definite silvery markings

Rose America.—Judging from the splendid blooms on view, this American variety has a great future and the introducer is fully justified in terming it "a wonderful Rose." The quite full, shapely blooms are carried on exceptionally long erect stalks. The petals are broad and substantial

Gossamer.—A narrow petalled exhibition Cactus of good form. It is of pale mauve colour with a very pale centre.

Doris Trayler.—A handsome dusky Decorative variety. The deep crimson colour is heavily flushed with maroon.

THE FRAGRANT NEW ROSE AMERICA WITH SILVERY ROSE BLOSSOMS.

GORGEOUS CRIMSON SPRAYS OF THAT BRAZILIAN LEGUME ERYTHRINA CRISTA-GALLI.

along the midrib and veins. With age, the colour darkens and the silvery markings lose their sparkle, but the leaves are still decorative. The flower stems are only a few inches high and from them hang two or three white flowers, almost like miniature Hoya carnosa flowers. *C. maculata* was introduced from North America in 1752 and for a considerable time was known as *Pyrola maculata*. It "thrives in thin, mossy copses, on light, sandy, vegetable soil, or in moist and half shady parts of the rockwork or fernery." It is propagated by division. Shewn by Mr. G. Reuthe.

Dianthus Allwoodii Clarkson Pink.—This variety is quite distinct from the remainder of the free-flowering "Allwoodii." It is rather larger, more shapely and of delicate pale pink colour. The fragrance was slight. Award of merit. Shewn by Mr. G. Miller.

Gladiolus Poppy.—The name scarcely does justice to the sparkling scarlet colour of this strikingly handsome variety, and this colour is enhanced by the purple and white markings on the two lower segments. It is a compact, medium-sized spike. Shewn by Messrs. Lowe and Gibson.

Montbretia Cecil.—This is quite the best of the yellow varieties. The flowers are of rather more than average size, they open well and are well disposed on the spike. Award of merit. Shewn by Mr. S. Morris.

and of good pink colour with a darker centre. The foliage is a dark glossy green and the blooms are delightfully fragrant. This should be a splendid florists' Rose. Award of merit. Shewn by Mr. Elisha J. Hicks.

Rudbeckia purpurea elegans.—This variety is a great improvement on the type species. The flowers are much larger in every way, the colour is richer and the florets stand out well instead of quickly hanging down, as in the species. This new variety will provide a welcome change of colour in the herbaceous borders at this season. Shewn by Mr. Amos Perry.

NEW DAHLIAS.

The Joint Dahlia Committee, which met for the first time this season, selected the following novelties for trial at Wisley next year from the large number which was submitted for consideration.

Gloria.—A magnificent Decorative bloom of large size and crimson colour, flushed with maroon.

Martin.—Another good Cactus with a yellow centre and flushed outer petals.

Miss Edith L. Jones.—Somewhat similar to the previous, but of deeper colour and with very long stalks.

Periscope.—A rosy purple Cactus of starlike form and borne on long stems.

A. E. Amos.—A very shapely Cactus with narrow incurving petals of dark coral red colour. The flowers are well carried on stout stems.

John W. Woolman.—A well set up Cactus with long, incurving petals of pale yellow colour which is flushed with rose when mature. The above were shewn by Messrs. J. Stredwick and Son.

Rosie.—This is a very beautiful rosy mauve Miniature Paeony, but as the name has already been used it will have to be changed. This and the next three Dahlias were shewn by Messrs. Jarman and Co.

Joyce Goddard.—A vividly beautiful garden Cactus variety. The rich scarlet petals are coloured bright yellow at the base.

Betty.—A very pretty pale lilac Pompon of good form which will be a welcome addition to these dainty flowers.

Gold Cup.—Another desirable Pompon Dahlia. It is of medium yellow colour.

Hindhead Star.—A very decorative variety of good shape and buff colour shaded with rose at the tips. This and the two following were shewn by Messrs. J. Cheal and Sons.

Haslemere Star.—This may well be termed an improved Southern Star and so is of value.

Vesuvius.—A brilliant miniature Paeony of deep scarlet colour, shaded with crimson.

SOME SHRUBS OF LATE SUMMER

THE sweetest Roses of the year may often be found among the Rugosas from August onwards, and of these I think the first place must be given to Blanc Double de Coubert. The large blossoms of this fine old variety are, when fully open, a pure, cold white and, as the flowers open flat, they disclose a central tuft of yellow stamens. The foliage is of a peculiarly fresh green and the beautiful buds, faintly shaded with shell pink, open well in water and fill the room with their refreshing old rose perfume.

Rosa rugosa Conrad F. Meyer, in a lovely silvery rose and delightfully scented, is a worthy rival of the foregoing, and there is something very taking about the loose bunches of semi-double pink blossoms borne by *R. r.* Belle Poitevine. Mrs. Anthony Waterer, which appears to be a hybrid, also yields fine late blooms in a bold cerise and they are not less fragrant than those of the rest of the clan. *R. lucida* has been very beautiful in the woodland throughout July and looks like continuing in flower for some time to come, and there are some rambling masses of the creeping *R. Wichuraiana*, whose glossy foliage is now adorned with lax clusters of star-shaped white flowers. This is a delightful Rose for the right place, and there is a variegated form of it which, though not nearly so rampant a grower, is worth a good place. A good deal of pink suffuses the creamy variations of this variety, especially in the young shoots.

Although Veronicas of the *Andersoni* set, with their fine foliage and large bottle-brush flowers in almost every conceivable shade of colour, other than yellow and orange, are reliable late bloomers and distinctly showy, they cannot be depended on to stand the winter here, even though we are no more than five or six miles from the western sea. Moreover, I am never quite sure that these shrubs fit in with the majority of woodland and garden plants sufficiently well to merit the risk involved in growing them. They seem more at home in the walled gardens of the seaside resort, and perhaps it is because they are so widely grown in such places that one cannot raise much enthusiasm about them. Yet the pure white *Mt. Blanc* is very attractive; *Gauntlettii*, salmon pink, is a pleasant change from the heavy purples, wine reds and mauves, and there is a rosy pink variety of the same class as the well known deep violet *Autumn Glory*, which is uncommon and distinctly good.

V. salicifolia at its best is one of the most popular of the taller shrubby species and it is quite hardy here, seeding about the woodland as freely as *V. Traversii*, but it is not, to my eye, so attractive as the latter. A vigorous young plant of *V. Traversii* (an earlier bloomer), well furnished with its multitudinous spikes of white, delicately shaded with a hint of blue, can be a really handsome bush that will hold its own with the best of companions, and it is, moreover, the hardiest of its race. There are, however, good and bad forms in *V. Traversii*, many of the seedlings which this species produces so abundantly being poor and weedy in the blossom. Once this plant gets leggy, which in the course of time it inevitably does, it should be replaced by young plants, for it does not often break satisfactorily from the base after cutting back.

The shrubby Hypericums comprise a group of species and varieties of the utmost value in the late summer garden. The pick of the basket is probably *H. patulum* Henryi, which produces during August and September a prolific crop of golden-yellow flowers, often nearly 2 ins. across and of remarkable firmness and texture. This attains the height of about 3 ft., and near it comes the more compact *H. Hookerianum* (oblongifolium), with narrower

leaves and rather smaller flowers. Both of the above are said to be somewhat tender, but we have never had them injured in the slightest degree and, like most of their kind, they do well under the shade of deciduous trees. *H. hibernicum* is a

THE RED BOTTLE-BRUSHES OF *CALLISTEMON SALIGNUS* (*METROSIDEROS FLORIBUNDA*).

heartly, free grower—perhaps too free sometimes—for the woodland or wild garden, and it is by no means unattractive when its dense mass of slender, wiry, 3 ft. growths are crowned with their small, upright, yellow blossoms, each with their conspicuous "brush" of stamens. There are several other species, American and Chinese, which are much after the pattern of *hibernicum*; and *H. trifolium*, with larger flowers, has been strongly recommended by those who grow it. There is, however, an extraordinary similarity, to the average eye, between all these *St. John's Worts*, and those mentioned may, I think, be considered fairly representative of the genus. *H. Moserianum*, rather earlier and much more dwarf, is practically in a class by itself, and very beautiful and distinct it is. It is a hybrid between *H. patulum* and *H. calycinum*, with all the fine attributes of the former and none of the latter's sins. *H. tricolor* (Richeri), whose leaves are splashed with crimson, white and green, is an interesting little plant of about 1 ft. for those who have a fancy for such things.

Desfontainea spinosa is a remarkably handsome shrub which, under congenial conditions, will grow to a bulky bush of 8 ft. or more in height. It usually opens its first flowers here in early July and continues in full bloom right to the "back-end," the waxy, crimson-scarlet bugles, about 2 ins. long, with their brilliant yellow throat and lip, creating a most gorgeous effect against the dark green, holly-like foliage. In not a few gardens this fine plant has a way of getting shabby with age and it often dies piecemeal just when it has attained a good size. This failing is usually foreshadowed by an extraordinary crop of blossom and the shrub is then said to have "flowered itself to death." But it would probably be nearer the truth to say that this excessive production of flower was itself

a symptom of some loss of vitality attributable to defective root action. From what I can gather from my own experience and that of others it is soil exhaustion, coupled with drought—practically synonymous terms in one sense—that causes *D. spinosa* to go off in the manner suggested. Specimens in rather heavy soils of the old kitchen-garden variety never seem to suffer, but flourish abundantly

for many years. So, with that in mind, we intend trying *D. spinosa* on a good bed of vegetable compost and old cow manure instead of our natural woodland loam.

Enkianthus cernua rubra is a shrub that has done more sulking than anything else here, though its autumnal leaf-colouring has always been very gorgeous. With this, however, the error was more than likely in the planting, for the solitary specimen now in possession was put in a place where the soil contained a good deal of lime. Being an Ericaceous species, this shrub would probably object to such fare, but it would be interesting to know how others have succeeded with it. Another shrub which has thus far disdained our most patient attentions is *Abutilon vitifolium*. This has been tried in all manner of soils and situations, but on every occasion it has turned us down. It would not be quite so bad if it would promptly die outright, but it prefers to languish, and a plant that does that is not a pleasant companion. What makes it the more exasperating is the fact that *A. vitifolium* flourishes like the proverbial Bay tree in a neighbour's garden where conditions appear to be similar to our own.

Very different is the case of *Sollya heterophylla*. This charming little twining shrub came into bloom quite early this summer, it is full of blossom to-day and looks like carrying on far into autumn. There is a singular daintiness about *S. heterophylla* which is irresistible. The pretty twist of its myrtle-like leaves on their slender, spiral wands, the elegant, hairlike flower stems and, swinging at their tips, the little bells, which on first opening are a beautiful speedwell blue, together make an object of surpassing loveliness. Then this delightful thing is, as I have suggested, as hearty and easy-tempered as a Scotch Fuchsia, but it is not quite

so hardy and should be given a warm wall in most places.

Another twining shrub of the highest merit is the Chilean *Berberidopsis corallina*. We have this against a north wall and it is now opening its coral-red, pendent flower clusters, for which the fresh green, leathery foliage affords an admirable backing. This is probably a good deal harder than is generally supposed. It appreciates a cool root-run in old vegetable soil or well-rotted cow manure and turf loam.

Of the shrubby Sages, *Salvia Greggii* from the mountains of Texas is a hardier species and a better bloomer here than the old *S. Grahami*, but it also needs a light, warm soil and does not flower as freely as one would wish, save during exceptionally fine autumn weather, when it will often put up a good display of its geranium-red blossoms. Allied to the Sages is *Perovskia atriplicifolia*, a really choice shrublet of about 4ft. in height with silvery-white stems and leaves which are strongly aromatic. This appears to do best in a warm, sunny, open spot that is not too dry in summer. The flowers, which are borne at the ends of the new growths in slender panicles, are a clear violet-blue and nestle in a setting of white wool, which gives them a distinct and attractive appearance.

CORRESPONDENCE

CALEOLARIA AMPLEXICAULIS FOR BEDDING.

THE fine beds of the herbaceous annual *Calceolaria* were so much admired last June in the park that gardeners are becoming aware there are other members of the family beside the too universal bedding yellow *Calceolaria* so dear to old-fashioned gardeners. They almost invariably edge it with dark blue *Lobelia* and in consequence, make it abhorred by those who are sensitive as to shades and colours in their gardening! *C. amplexicaulis* is a well known and beautiful plant for summer bedding, but its growth is rather lanky and young plants are not very free flowering, so it is not grown as much as it deserves—and here comes my point. I saw a splendid big bed of this fine old plant on the breezy (shall I say windy?) esplanade at Scarborough the other day. The plants, tied to sticks, were over 2ft. high and smothered in flowers; I never saw such a splendid show. On enquiring of the Borough Head Gardener, I found that this big bed was planted last year and that it *survived last winter* without protection! So beautiful a bed, with its sheaves of flower, was happily planted on a groundwork of *Verbena venosa*, which equally stood last winter's storm. Such a combination deserves to be repeated in all seaside gardens where they are free from heavy, damp dews and will, I trust, be perpetuated both here and elsewhere, though a severe winter would, no doubt, kill the *Calceolaria*. The dry and wind-swept gardens of our south-east coast will prove especially suitable for such a plant. Another semi-hardy plant also deserves notice. There are several forms of *Fuchsia triphylla* which are quite as hardy as most *Fuchsias* commonly grown at the seaside and I saw a fine plant of it that had stood for three years on a sunny bank in such beauty that its tall shoots with fine foliage crowned with abundant sprays of drooping coral flowers made the *Hydrangea* bushes look hopelessly commonplace and dull. I for one shall hope to see masses of it near the *Agapanthus* which are now just in flower—a more brilliant and fairly lasting combination could not be found. The growth of these *F. triphylla* hybrids is so much more vigorous on old established plants that it is also a lesson for gardeners on the Riviera, where it will flower in autumn and spring.—E. H. WOODALL.

The shrubby *Eupatorium Weinmannianum* does not come into one's garden with any very convincing testimony as to its worth. Its undoubted tenderness stands against it no less than does its relationship with some of the weediest of composites. But its broad corymbs of fragrant white flowers are produced at the head of the 3ft. to 5ft. stems throughout the autumn, and these the butterflies love no less than the crushed strawberry pads of *E. cannabinum*, the Hemp Agrimony, our only native species. Therefore, since a plant that brings September butterflies to the garden has to possess a malignance that is wholly unpardonable before it is cast into outer darkness, it is probable that this *Eupatorium* will be accorded hospitality for as long as it pleases to abide with us.

Also on its trial is *Metrosideros floribunda*, not that this gorgeous shrub is ever likely to lack appreciation, but it has not yet stood a winter severe enough fairly to try its constitution. Albeit a young specimen of this Australian has so far promised most favourably, making not only vigorous growth, but a number of heads of flower. These fuzzy, bottle-brush inflorescences are about 6ins. long and positively blaze with a fiery red that tends to a glowing crimson in a subdued light. N. WALES.

A FINE SPANISH CHESTNUT.

I AM forwarding you a photograph of a large Spanish Chestnut tree growing at my home, New Plymouth, N.Z. The branches span 93ft. and the circumference round the growth of the tree is 279ft. The diameter of the bole is 5ft. 4ins.

A SPECIMEN SPANISH CHESTNUT, *CASTANEA SATIVA*.

The tree is growing steadily and is a fine specimen, and I thought it might prove of interest to you.—NEWTON KING.

LATE-FLOWERING TULIPS.

THE Rev. J. Jacob always writes upon such a diversity of topics other than gardening, from a bricklayer's taste in liquor to the wardrobes, if any, of goddesses—was not yellow, by the way, reserved for an entirely different class of young

woman?—that I suppose he can never find space to repeat his useful plain-sailing bulb lists, with straightforward descriptions and simple directions. Years ago he gave us a Tulip selection that was useful and to the point, even though, years ago, it was verging on the anachronistic.

Since that day May-flowering Tulips have increased and multiplied; here and there we may get a fleeting hint of their later novelties, but for the most part your worthy specialist, so garrulous on other subjects, remains willfully taciturn on what should be an inexhaustible topic to him. Does he keep a blind eye for all those wonderful Dutchmen's catalogues with their laconic descriptions of "shot" and "violetish"? Or do they leave him cold? Has he never tried to find a decent substitute for the dull sobriety of the Rev. H. Ewbank?

Is he satisfied with the forced cheerfulness of John Ruskin, which always gives one the impression of a man protesting that an east wind is the best of all possible weathers? Surely we want something better than these and other Victorian types, so much beloved of English growers. Even now most of them do not list Bronze King or Panorama, and I suppose it will be twenty years before Vulcain or St. James comes on the English market. The trouble is that the English grower gives us too little, the Dutch too much. When will our specialist come along and give us an up-to-date, distinct and unassailable selection, a genuine glowing purple, a pure lavender or an admissible blue? For my part I can only say that I have tried many and failed often, and I hope someone else, if not Mr. Jacob, will make an effort to bring us up-to-date. Beyond the forms already mentioned—and of these Vulcain is not worth its present price—Doni Pedro, Moonlight, Massenet and Clara Butt,

I am not convinced that any of the later Tulips can be called ideal, but I do not profess to anything like universal knowledge.—R. S.

THE PUSCHKINIA.

WE have few prettier hardy bulbous plants of spring than the Puschkinias, or Striped Squills, which are charming for the rock garden, for planting in grass, or for groups near the front of the herbaceous border. They are little

scilla-like flowers and, indeed, closely allied to the Scillas. Of the two species recognised in the "Index Kewensis," only one appears to be in commerce. This is *P. scilloides*, which is synonymous with *P. libanotica* and *P. siculus*. It is very frequently catalogued as *P. libanotica*, and a

meal-eatable good. Unfortunately, it looks very much like the rest of the slugs and how or why it became carnivorous instead of vegetarian I do not know, but the delightful truth remains that while others are greedily gobbling up one's precious seedlings and young Lettuce, the Testacella is waiting to gobble up them. When one finds a long, fat, juicy beast, with "slug" written all over him, crawling at night among one's choicest seedlings, it is not unnatural to slaughter without further enquiry, but it is unwise. The Testacella has a small oval shell on the point of the tail, the hall-mark of respectability among an otherwise disreputable race. It is astonishing how quickly one gets to recognise this distinguishing mark and one is quite safe in sparing all who bear it.—CROYDONIA.

winter-flowering species, coming into bloom in late October and continuing until spring is well in. That, at any rate, is what it may be relied upon to do in any of our milder counties. It is not a tender species, but as its blossoms are apt to be spoiled by wintry weather, it makes a more satisfactory cold-house plant in all but our favoured localities. In foliage and habit *V. difformis* is much like *V. major*, but it does not appear to spread so rampantly as the latter. The blossoms, about 1½ ins. across, are singularly lovely, being a cold glacier white suffused with a very pale wash of violet and the segments of the corolla are sharply pointed to one side, thus giving the flower that "whirling" appearance seen in some of the lesser Periwinkles. The present is a favourable time for planting. In selecting an outdoor site a partially sheltered spot in light, gritty loam should be chosen.—T. C.

NOTES FROM A WEST-COUNTRY GARDEN

ALTHOUGH one's garden never looks more dejected than it often does for some days after heavy rain has broken up a July drought, and although there is an unmistakable smell of autumn rising from the wet earth, it is still only August. Among the many rather pinched-looking individuals which have been shrinking under a pitiless sun for a month are some survivors and late bloomers which help to bridge the gap that lies between summer and the "season of mists and mellow fruitfulness."

Gentian septemfida is one of these, and a valuable plant it is, not only because it is often at its best during this off-time, but because it is both reliable and extremely showy. Given a good bed of this fine Gentian you may count upon having a gorgeous display of blue for five or six weeks, and one that will recur every season for years without the plants receiving any attention beyond a spring top-dressing of leaf-mould and loam. We have a couple of square yards of *G. septemfida* in extremely light soil and close to the top of a retaining wall some 10 ft. high. Yet the plants, now a dozen years old, never fail us and many of the heads carry as many as fifteen blossoms. The trailing form of the same thing, known as *G. Lagodechiana*, is no less beautiful, if not quite so free and robust. Like the type it is a clear, yet bold, azure, and the prostrate, leafy stems with their upturned blossoms are extremely elegant.

The magnificent *G. Farreri* is not so satisfied with us as the foregoing, though it has a reputation for good temper with so many; but with this, as with many other plants, it is probably a matter of finding the right spot—for it is indisputable that there are a number of plants which, no matter how much patience is bestowed upon them, refuse to be comforted in some gardens until they are put into a place which is to their liking. Soil, aspect and treatment may appear to be identical in all spots, yet they will flourish in one and sulk in another.

Gentiana Pneumonanthe, the Marsh Gentian or Calathian Violet, also opens its flowers in August. The form we have here is one collected from a West Country bog, and though the flowers—sapphire and emerald Harebells with green stripes—are like that of other types I have seen, they are borne singly, one on each stem, the latter being unbranched. Another admirable plant in blue for the August border or rock garden is Buxton's

PHILADELPHUS LEMOINEI ON A WALL.

variety with denser trusses of flowers is generally sold as *P. libanotica compacta*.

The stems are from 4 ins. to 8 ins. in height, the leaves being from 4 ins. to 6 ins. in length, lance-shaped, channelled and of a dark green colour. The flowers, about an inch in diameter, are generally white or very pale blue, decorated by a distinct deep blue stripe down the centre of each segment. The variety *compacta* is more effective than the type, but is rather less graceful. The Puschkina is not at all difficult and will flourish in a light, well drained soil in a warm situation, where it will prove hardy. Some recommend peat, but this is not necessary. It is one of the bulbs which should not be too long out of the soil and should be planted as soon as obtainable in autumn at a depth of 3 ins. or so. I have sometimes covered the place with light litter for the first winter, but it does not seem absolutely necessary to do this. Slugs occasionally destroy the flower buds as soon as they appear. *P. scilloides* is a native of Asia Minor and adjacent countries.—S. ARNOTT.

A GARDENERS' FRIEND.

YEARS ago I used to destroy everything that looked like a member of the genus slug. There is, however, a slug that should certainly be encouraged, for it is carnivorous and preys upon lesser members of its brethren and therefore does

AN UNUSUAL WALL SHRUB.

I THINK the enclosed picture of *Philadelphus lemoinei* as a wall shrub may interest some of your readers who only know it as a not very tall bush. Of course the usual method of pruning—to cut out the old wood to the base immediately after flowering—has to be considerably modified when the plant is grown in this way, but it is quite easy to grow and train.—H. C. W.

A BEAUTIFUL BAMBOO.

THE strikingly handsome *Arundinaria auricoma* is never quite

so beautiful as it is during the later summer and autumn, for its foliage is then at its fullest and best. This is a Japanese species of about 4 ft. in height, with dark purplish stems and an abundant foliage, the leaves being from 3 ins. to 6 ins. in length and up to 1 in. broad. The most remarkable feature about the plant is the leaf colour, this being a fresh green, conspicuously striped with yellow. In some instances the leaves, which are silky when young, may be almost entirely devoid of green, but the two colours are usually about evenly divided and arranged either in broad or thin lines or in both. Though it is inclined to spread by suckers in some soils, *A. auricoma* can generally be trusted to behave in this way with much more moderation than many of its kindred. It does not insist on anything better than ordinary, moist, well drained soil, and will often thrive for years in woodland loam that is anything but damp in full summer. *A. auricoma* is, moreover, a fairly hardy species and one that may be tried wherever *A. japonica* (Metake) will thrive.—N.

A WINTER-FLOWERING PERIWINKLE.

IF the merits of *Vinca difformis* (acutilorata) were better known, there is no doubt that it would be more widely grown than it is. Its chief value lies in the fact that it is a

variety of *Geranium Wallichianum*, a perennial of undoubted hardiness and one that delights in any free loam with or without lime. Although this splendid form is so infinitely superior to the type, it is still uncommon, and this is the more remarkable when one realises that it comes fairly true from seed. That is to say, you will get in a batch of seedlings a majority of plants whose saucer-shaped flowers are of that pure nemophila blue which distinguishes the variety from the dull reddish purple of the original.

This is also the season of the genus *Ceratostigma* (*Plumbago*), and there are few better plants for a warm, sunny corner than *C. plumbaginoides*. We find that this species does best wedged in among stones under and about which it can thread its wiry roots and send up its bunchy tufts of roin. growths which terminate in the lovely blue flowers. This is quite hardy in light soil and a free bloomer with the sort of root-run I have described. The flowering period extends well into autumn, when the foliage assumes brilliant tints of crimson and orange. In *C. Willmottianum*, which grows into a bush of a couple of feet or more, and which does not appear to run like *plumbaginoides*, the leafage and flowers are both smaller and the blue of the latter hardly so intense.

MOST GORGEOUS OF GENTIANAS, THE SOFT YET BRILLIANT BLUE GENTIANA FARRERI.

Although *Raoulia australis* appears to be indifferent to drought, it is a moraine plant and one that usually waits for heavy rain about this season before it flowers. Some humpy masses of this pretty carpeter, which are so firm and close-set that they resemble the heads of lichen boulders, broke out into an eruption of tiny ivory beads within two days of the weather changing. There were few objects in the rock garden more attractive than these when those ivory knobs dappled the silver mail with little puffs of gold and some dainty, half-bred Harebells hung their pale azure flowers over the sheeny, metallic-looking mounds.

Cyananthus lobatus is an August bloomer of no little distinction, and for some years it has proved quite permanent on a well drained ledge that is not too dry. It is a pleasant little plant with prostrate branchlets of small, hairy leaves

each of which terminates in a conspicuous violet-blue blossom. *C. incanus* is another species of more slender proportions and more delicate in line.

Some of the *Potentilla*s may always be depended upon to give colour during the holiday month, and the most gorgeous is *Potentilla argyrophylla* Gibson, the well known "Gibson's Scarlet," a plant of the highest quality where a large, sprawling mass of pretty foliage and brilliant scarlet flowers is desired. *P. atrosanguinea* is also of this set and a valuable border plant, but a better thing than any of these to my mind is *P. nepalensis* (*formosa*). This because it is an all-season bloomer, the large, black-eyed, rosy-cerise flowers are of an unusual and good colour, and the plant is an easy doer anywhere. For the rock garden there is a dwarf form of the above, *P. n. Willmottiae*, a delightful little plant of no more than 6 ins. high, often less, and with even larger flowers than those of the type and of a more brilliant colour. *P. Tonguei* will often come into flower again at this season, and this again is a diminutive *Potentilla* of the greatest charm, with flowers of a soft apricot-buff, deepening to a crimson zone at the centre.

One of the most satisfying masses of colour in a mixed border during the last few weeks has

from seed. A group of *S. virgata*, with its bold heads of violet, will always produce a telling effect in the August border, and there are many other excellent kinds, not forgetting the incomparable *S. patens*, which may be counted as hardy enough for wintering outdoors in many West-coast gardens.

It is at this season that that strange Japanese plant, *Kirengeshoma palmata*, comes into flower. Though among the first of the herbaceous things to appear in spring, it takes all summer to produce its 2 ft. ebony stems with their broad, *Spiraea*-like leaves, which terminate in the curious flower sprays. These latter consist of a loose, branching cluster of somewhat pendent flowers, about 2 ins. in length and of a soft ivory yellow. The blossoms suggest some pale Marigold waiting half-opened for the sun, but they never get beyond the shuttlecock shape and, like Primroses, "die unmarried" on the threshold of winter. *K. palmata* is, nevertheless, a handsome and interesting plant for a cool, half-shady spot, and its autumnal leaf colouring is by no means the least of its attractions.

Whether they are in the border, woodland or wild garden, the old Evening Primroses—the large-flowered type—must always be reckoned among the best of late summer and autumn flowering plants. They are so stately in habit, their colour is so good and their fragrance so refreshing that that familiarity which is said to breed contempt can never lessen the affection with which they have come to be regarded by most of us. Their splendid and hearty vigour, their indifference as to whether they are in sun or shade, and the quiet and commendable manner in which they will maintain a fresh stock of self-sown seedlings for each year's flowering are also attributes which have helped the Evening Primrose to hold its own so successfully against the inrush of novelties.

Among the tall Campanulas for the woodland or shrubbery of the later summer few can give such a charming effect as *C. lactiflora*. Individually, the plant might be eclipsed by many, but there is a strangely fascinating beauty about a mass of this elegant species when the curiously luminous azure of the bold flower-heads gleams like a blue autumn mist in the shadow. A. T. J.

SCENTED LUPINS

SHEER amazement is the only feeling of which one can be conscious when standing before an exhibit at a flower show of the modern Lupin in its full glory, a sensation that is only intensified when memory begins to work and recollection of the varieties of but a few years back comes vividly before the mind. Who could or would have supposed that so much latent possibility lay behind the modest spikes of white, blue and purple, with which we were all so familiar? It was a beautiful flower then (when it did not disappoint by shedding a good third of its buds unopened), but to-day words absolutely fail to convey any adequate picture of the marvellous range and beauty of the colours displayed. This, however, is not all. Nature, when she is encouraged by the hand of the hybridist, is apt to overflow with bounty and in the case of the Lupin she has, as her latest and best development, given us a series of perfumed forms. This is not a faint washy odour, but a delicious and unmistakable perfume that fills the air all round where they are growing. The colour range is not restricted in this remarkable break, for every shade of white, blue, mauve, purple, crimson, pink and yellow is represented and one is only left wondering what surprise this remarkable plant can now have "up its sleeve" for us. C.W.

INSECTIVOROUS PLANTS.—I

THAT all plants are wonderful is a truism that anyone who has studied them ways—even to a superficial degree, is compelled to admit. What, then, are we to say of this remarkable class that, in addition to getting its living in the ordinary way by means of the roots and leaves, has gone further and evolved a series of cunningly baited traps which capture insects? Not is this all. There is a definite purpose for which those insects have been trapped—a larger supply of nitrogen; but this nitrogen can only be obtained if there is an elaborate digestive apparatus to deal with and absorb it. Let me now say a few words about the means of digestion before we proceed to examine individual plants and the means whereby they attain their ends.

In all cases there is much that is analogous to the human stomach—so much, indeed, that we find the division between the plant and animal world wearing very thin indeed. Whether it is the liquid contained in the curiously elongated "pitchers" of the *Nepenthes* or the sticky globules of the *Sundew*, the "bait" or fluid, by which the unfortunate insect is tempted to its death, becomes acid immediately a "catch" has been registered. This conversion of the digestive fluid into an acid, immediately there is anything to "eat," changes the nature of the insect's body into such a condition that the plants can use it for themselves. Analysis of the liquid, so commonly referred to as water, in the pitchers of the *Nepenthes*, shows that various acids are present—malic, citronic and formic acid—as well as a peptonic ferment as in the animal stomach and yielding the same result. In the *Sarracenia* the fluid in the long, upright pitchers appears to be devoid of digestive power, but accelerates decomposition, so that, ultimately, the ends of the plant are served: for, when the pitcher dies and falls over to the earth, it carries with it a rich store of nitrogenous manure ready for the roots. With the *Pinguicula* or *Butterwort*, a greasy secretion is poured forth from the leaf surface so that it appears as if covered with hoar frost, and, if we enquire into the composition of this once again, we shall find that it is a solvent capable of digesting the captured prey. The *Sundew*, agile with glistening glands that appear like drops of honey, first sticks its prey by its glutinous powers, then pours over it a digestive acid fluid. *Venus's Fly Trap* attracts again by rosy red digestive glands which, immediately they are warned by the touching of the sensitive hairs, pour forth an acid digestive, while the leaf itself closes together in from eight to ten seconds.

It will be clear from all of this that the insectivorous plants are feeding upon a much higher chemical level than the majority of plants, and it may come as a surprise to those who have only met a few of these freaks to know that no fewer than 500 species of plants are known to have adopted "flesh eating" as an addition to their larder. In every case it seems to be that they have adopted this strange method of adding to their store of nitrogen because they grow in peat, a staple that is notably deficient in this essential of plant life, though why some species have adopted it, while others have not, seems to be impossible of explanation.

Before we leave the subject of insect catchers in general, let us take a glance at the methods of trapping that are employed. These may be broadly separated into three divisions. In the first of these are placed those which form pits or cavities into which ingress is fatally easy, while exit is well nigh impossible. Every possible inducement is offered to entice the insect within that fatal death chamber. Examine the interior of the

pitchers of many of the *Nepenthes* and you will find that the lip is plentifully besmeared with nectar. Note, too, that this is so placed that it is unobtainable until the creature has been induced to enter the danger zone. This danger zone varies in the means of inducing, for in some cases it is highly polished and of wax-like smoothness. In others, the way to the nectar below—or apparent nectar, for the whole appearance is often mere delusion—is paved with rows of downward pointing hairs, over which it is delightfully easy to walk until one turns and finds oneself faced by a formidable barricade of bayonets against which it is impossible to make any headway. So, either by a staggering slide which precipitates the insect into the death pool beneath or the no less sure, soft and easy telted road, but along which there is no return, the insect goes to its death—and the plant gains its nitrogenous meal.

The second division relies for its captures upon what at first sight appears a far more primitive system—in short, the sticky flypaper. But pause a moment, before we dismiss the subject so lightly. Those glittering drops of moisture or those greasy-

feeding leaves of the *Butterwort* are backed by the formidable digestive juice which—as soon as there is anything to eat—flows forth and disposes of the nitrogen collected by the "flypaper."

Third and last is the most wonderful group of all these plants which, in addition to stickiness and digestive powers, have added that of movement. Both the *Sundew* and *Venus's Fly Trap* exhibit this remarkable power of movement. No sooner is one of the extremely sensitive hairs touched by an insect than it at once begins to close downwards; and, more remarkable still, other hairs in the immediate neighbourhood seem to receive a telegraphic message for aid, for these, too, at once begin to bend *boards* and close down upon the capture. Now, those sensitive tentacles are endowed with an almost uncanny power of discrimination. Bits of sand, stick or other small particles, do not provoke any response whatever—the leaves remain as before and nothing happens. The tiniest speck of animal food, however, immediately wakes those resting powers, the acid digesting fluid is poured forth and the "plant" literally gobbles the dainty morsel. In future articles I propose to deal with some of the most remarkable examples of these insect-devouring plants, with cultural details.

H. W. CANNING-WRIGHT.

THE SHRUBBY HYPERICUMS

THE *Hypericum* (St. John's Worts) only need to be planted and given fairly good treatment for their beauty to be appreciated and their usefulness fully to be admitted. About twenty years ago I saw *H. calycinum* planted to form a carpet in a large bed where specimen *Rhododendrons* were grown. The position was a quite open one and the soil, if I remember rightly, rather stiff loam, but there was no doubt as to the plants being at home there. A few days ago, when judging at a flower show in South Hants, I saw this *Hypericum* in two quite different positions and soils. One was under taller-growing shrubs—in partial shade, too; the other was in a raised border in a hot position and without shade from the sun. In both instances the plants were thriving and flowering freely. There are so many borders in gardens generally where the *Hypericum*s would thrive, and the lovely flowers and beautiful foliage both last so long in a nice fresh condition. The following are some of the best kinds to grow: *H. Hookerianum*, strong growing and evergreen, bears large deep yellow flowers; *H. patulum* has curved or arched shoots, deep green foliage and medium-sized flowers; *H. calycinum*, of spreading habit, is

nearly evergreen and succeeds well under trees, either as an edging to a drive where large specimen trees abound or as a true carpet plant under choice shrubs; *H. Moserianum* has very large flowers, rich yellow and shews to best advantage when planted about 1 ft. apart to form clumps near the front of a large border. I am praising the beauties of quite old garden favourites, but I am sure readers who also know the plants and love them will feel I am justified.

GEO. GARNER.

THE ROSE OF SHARON, *HYPERICUM CALY CINUM*.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Cauliflower.—Another small sowing of Cauliflower should be made during the next week or ten days and, should the weather prove severe, the resultant plants will probably stand the winter better than those sown earlier. Directly the early batch is ready the seedlings may be picked out in nursery beds or planted about 18 ins. apart on a warm border. A sturdy, short-jointed growth should be encouraged.

Parsley.—If seed was sown some weeks ago the seedlings will be large enough for thinning. This may be done gradually by pulling out complete plants as Parsley is required for the kitchen.

Spinach.—The winter variety of this useful vegetable constitutes an important crop, especially in large gardens, and at the present time the soil between the rows should be hoed occasionally to keep down the weeds. When the seedlings are large enough, thin them to ones. If for any reason the seed has not germinated freely, another sowing should be made without further delay. In cold districts a warm border should be chosen.

Lettuce.—At this season Lettuces are usually plentiful, but it will be necessary to look ahead if the supply has to be kept up. Seedlings that are large enough may be transplanted in lines 1 ft. apart, and another sowing of both Cos and Cabbage varieties should be made. Select hardy kinds, such as Continuity and Bath Cos. If Lettuces are in great demand it will be advisable to make a liberal sowing during the early part of this month. Later on some of the plants may be transferred to cold frames.

The Flower Garden.

Propagating continues to demand attention and cuttings of Pelargoniums, etc., should be secured at the earliest opportunity until the requisite number are inserted. The present month is also a suitable time to take cuttings of various shrubs, such as Buddleias, Veronicas, Escallonias and Berberises. Select half-ripened shoots, cut them off at a joint and trim the lower leaves close to the stem. A cold frame or handlight, if placed in a partially shaded spot, will be found the most suitable for the cuttings. A layer of sandy soil should be placed in the frame and made fairly firm, when the cuttings may be inserted in lines a few inches apart. Each kind ought to be correctly named to prevent confusion later on. Keep the soil just moist and to this end it should be sprayed twice daily whenever the weather is fine. The lights should be closed for the greater part of the day, but a little air may be admitted for an hour or so during the forenoon.

Bulbs.—It is essential that the bulb order be despatched as soon as possible in order that the bulbs may be at hand when required for planting. A quantity ought always to be grown in the reserve garden to supply cut flowers, while patches in the grass are very effective. Both may be planted during the present month and, of course, later, but early planting is recommended when the ground is available, even for the May-flowering Tulips.

Roses.—The climbing or rambler Roses growing on poles and pergolas may have the old growths which have flowered cut out and sufficient new shoots should be tied in to produce flowers next season. Overcrowding should be avoided, the object being to get the new wood well ripened. New poles should be fixed where there is any doubt about them lasting another season.

The Hardy Fruit Garden.

Peaches and Nectarines.—Trees from which the fruit has been gathered should be examined and all useless shoots which have borne fruit removed in order to give the new growths a chance to become thoroughly ripened. Late varieties, the fruits of which are still swelling, may be given a soaking of weak liquid manure and, if the weather proves dry, all trees growing near walls should be afforded a copious supply of water. If allowed to get excessively dry at the base the fruit buds may fail to develop next spring.

Raspberries.—If not already done, the old canes that produced fruits this season should be removed at once, and this remark applies also to Loganberries and Blackberries. Retain sufficient new canes to produce a crop next season, always selecting the strongest and best growths. A dressing of manure may be given and future treatment consists of cutting away new shoots as they appear.

Fruit Picking.—Those who are fortunate enough to possess a crop of Apples and Pears should make an effort to gather them in good condition and prevent any waste. It may be necessary to go over trees several times and only remove those fruits that readily leave the branches. Store them thinly in the fruit room and place them on the stages without straw or any other material.

Fruit Under Glass.

Late Grapes.—Very few possess a suitable place to store grapes after they have been removed from the robs, so, to keep them as long as possible in the vinery, the bunches ought to be ripe by the end of the present month. All lateral growths should be pinched and a free circulation of air kept up by opening the ventilators, more or less, both day and night. Muscat Grapes may need a little heat from the hot water pipes to allow sufficient ventilation to prevent damping of the berries and to keep up a night temperature of 65°.

Vegetables Under Glass.

Tomatoes.—Where plants have been raised to produce a crop during the winter and early spring months they will now be ready for the final potting. Pots 10 ins. in diameter will suffice and ample drainage should be provided. A rich soil is not advised, but when the pots are filled with roots liquid manure may be applied. Grow the plants in a greenhouse and for the present admit plenty of air.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.)
Casle'ord, Cheps'ow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Spring Cabbage.—The sooner Spring Cabbages are planted out the better, so that they may get well established before winter. A quarter which has been cleared of Potatoes suits this crop admirably. No manure will be required at present and the only preparation of the soil that is necessary is to fork it over. On light soils even this is unnecessary; the soil, however, should be raked over. For Harbinger allow 15 ins. between the rows and 12 ins. between the plants in the row, and for Sutton's April, Flower of Spring, or McEwan's Vanack, allow 3 ins. more either way.

Potatoes.—Seed of second early varieties should now be sowed; select second-sized tubers for the purpose. While it is advisable to choose well shaped tubers for seed, it is a fallacy to suppose that their produce will, in turn necessarily be perfect. The shape of the individual tubers is quite accidental, the presence of a stone or a lump of stiff clay often accounting for malformation. Expose the tubers to the light and air for ten days or a fortnight before storing them.

Leeks.—Continue gradually to earth up Leeks in trenches as they develop. If collars have been employed, draw them up a little if necessary. Feed the crop lightly, weekly or bi-weekly, through the drain tiles inserted into the sides of the trench. It is advisable to change the feed occasionally, bearing in mind that all members of the Allium family have a preference for nitrogenous fertilisers.

Salading.—Thin and transplant Endive and late-sown Lettuce; both these plants should be accorded a place on a south border. Another couple of sowings of Radishes and Mustard and Cress may yet be made in the open.

Vegetables Under Glass.

Cucumbers should still be plentiful and, where the supply is in excess of the demand for present use, the surplus should be utilised or pickling. Continue to thin and stop the young growths. As female flowers open, it will be advisable to impollinate them artificially, more especially if the weather proves dull and wet.

Tomatoes.—Later crops will now be ripening their fruits and all available means should be employed to accelerate the process, as solar heat will soon be declining. One need now have less hesitation in removing any leaves or portions thereof that are obscuring the light from the fruits. Admit air freely on all favourable occasions and leave a little on all night. Allow a little heat in the pipes on dull days and also overnight, starting the fire sufficiently early to prevent any great drop of temperature as the sun heat fails. The plants should now be topped and all laterals promptly pinched out.

Fruits Under Glass.

Peaches and Nectarines.—As trees get cleared of fruit they should be vigorously syringed to cleanse both wood and foliage. Should thrip be present, fumigate the house with tobacco or apply it in liquid form through one of the various insecticides which are on the market. Go over late crops daily and carefully gather the fruits that part readily from the stalk. A catch-net should be provided, however, as, despite the closest attention, a certain number of fruits will drop of their own accord.

Figs. Second crop Figs will now be ripening off and all available means should be used to rush the process during the present month. Endeavour to maintain a dry, buoyant atmosphere with a fairly brisk temperature; do not hesitate to remove an occasional leaf if it is in any way excluding the light from a fruit or fruits.

Guava (Psidium Guava).—This tropical fruit is occasionally met with in Scottish gardens and its sweet, aromatic fruits are sure to be appreciated when produced; they are now largely imported into Britain in preserved form from the West Indies and from South America. The tree is of easy culture and succeeds well on the back wall of a vinery, a position which is not often utilised to best advantage.

The Flower Garden.

Sweet Violets.—A frame should now be prepared for the reception of these. They succeed best when raised 2 ft. or more above ground level. A spent hot-bed is suitable for the purpose and failing this, a bed should be made up of any loose material that will not ferment except in a very mild way. Place the frame on the bed and cover the bed with a foot deep layer of good sound loam. Allow the bed to settle for a week and then lift the plants carefully with good balls of soil attached and plant them in the frame rather closer together than they were in the open. Give them a good watering and make sure that all runners have been removed. At this stage it is a good plan to tack a lath of wood across the frame near the top and bottom to support the sashes; this ensures a free current of air in the frame which is essential, as the plants should on no account be coddled. Mat the frame for a few days if there is bright sunshine.

Pentstemons.—A start may now be made with the propagation of these popular flowers. Cuttings taken near the base are preferable to those produced higher up the stem, for although the latter are always thicker, they are not so well ripened and never produce such satisfactory results. Insert the cuttings in boxes firmly packed with sandy soil and place in a cold frame. Water with a rosed can and keep the frame close and shaded.

Brompton Stocks.—It is advisable to get these planted out into their flowering quarters without delay, so that they may get well established before winter sets in. On heavy soils a percentage of the plants generally succumb, so they should be accorded as favourable a position as possible. If the soil is in good heart no fertiliser should be applied until spring and in any case farmyard manure should not be used. If the soil is really poor give a light dressing of bone-meal. Plant about 1 ft. apart, using the trowel.

CHAS. COMFORT.
(Formerly Head Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian.)

GREENHOUSE AND CONSERVATORY.

Antirrhinums are excellent plants for growing in pots for conservatory decoration during the spring months and for this purpose they are worthy of more general cultivation. The seed should be sown in a cold frame towards the middle of the month. Find the intermediate varieties best for this purpose, as in their earlier stages they may be used for furnishing the stages and when they become too tall for the benches may be used in the beds. In their great variety of beautiful colours they are very useful for giving a supply of cut flowers. They should be sown thinly and pricked off before they become crowded in the seed pots. When large enough they should be potted up singly. If a good medium loam, without any leaf soil is used, their growth will be more stocky and sturdy; old mortar rubble may be used instead of sand to keep the soil open. The plants may be wintered in 48-sized pots, giving them a shift into 6 in. or 7 in. pots early in the New Year. They should have plenty of air and perfectly cool treatment at all times and may be grown in cold frames until they require more head-room, when they should be removed to a cool airy greenhouse.

Schizostylis coccinea. Commonly known as the Crimson Flag or Kafir Lily, this beautiful plant is more or less hardy in the South, when planted at the foot of warm walls. It however makes an excellent plant for pot culture, flowering through the autumn. Where stocks exist, strong clumps should be lifted some time during this month and placed in orn. pots. There is also a beautiful new rose coloured variety which is equally useful. One advantage of this plant is the fact that it may be successfully flowered in an unheated greenhouse. Where it is desired to grow strong stock for flowering in pots, the clumps should be divided into single crowns during the spring and planted out in the reserve garden, from whence they may be lifted and potted up during the autumn.

Tecoma alata (syn. *T. Smithii*) is now showing its flower buds and care should be taken to rub out the lateral shoots as they appear, for, if they are allowed to develop, the flower buds will fall off.

Bouvardias should be kept neatly staked and tied and pot-grown plants should be given plenty of air, as the cooler they are grown the more useful they will be later on for the greenhouse. Stock that has been planted outside should now be lifted and placed in suitable sized pots. Where quantities of cut flowers are required, it is a good plan to plant them out in a bed in a low house where they can be given a little heat; they will then give a supply of flowers over a long period. Considering how dainty and beautiful they are it is surprising they are not more generally grown at the present day. They are subject to attacks by *Begonia mite* which, however, is easily prevented by the use of the sulphur vaporiser. They also suffer badly from attacks by white fly, which should be kept in check with sodium cyanide or some other approved remedy.

Saxifraga sarmentosa is very pretty for the greenhouse, well grown plants in 48-sized pots being useful for decorative work. Runners should be secured at this time and potted up singly in small pots, in which they may remain until early in the New Year. It is also very useful as a basket plant, ordinary greenhouse treatment, of course, suiting it, as it is a favourite window plant. The variety tricolor is very pretty but requires a little more heat.

Abutilons, although not so popular as they used to be, are still very useful for furnishing the conservatory. Some of them are seen at their best when they can be planted out and trained over back walls or rafters. Most of them are somewhat dense for the roof and should be kept well thinned out. The slender-growing *A. vexillarium* and its variegated form are, however, ideal for draping rafters, as they do not unduly shade the plants beneath them. The hybrid *A. Milleri* is also very fine for this purpose and flowers with wonderful freedom practically all the year round. *A. insignis* is ideal for draping rafters in a large conservatory. Even if it never flowered it would be worth growing for its great rugose leaves. Its flowers are borne on long slender, drooping shoots, which makes it ideal as a roof climber. Well grown plants of *A. Thompsoni* and *A. Savitzi*, which are largely used for summer bedding, are very useful in the greenhouse during the autumn for mixing with other plants. They are all easily propagated at any time by means of cuttings.

J. COTTES,

Royal Botanic Gardens, Kew.

The Chinese Witch Hazel (*Hamamelis mollis*).—A shrub which, in the Home Counties at any rate, flowers regularly about New Year's Day, lasts a month or six weeks in beauty, and has a gracious perfume that is perceptible 3 yards or 4 yards away, is decidedly one of which note should be made. Such is the Chinese Witch Hazel. Each flower has several thin, narrow, rich yellow petals half an inch or rather more long. The flowers are without stalks and produced in clusters. The leaves are the largest among Witch Hazels, being roundish and 3 inches to 5 inches long, the lower surface covered with a soft down. It is undoubtedly the most of *Hamamelis*—in flower as well as in foliage. It was first discovered by Maries in the Yangtze-kiang Valley in China, about 1879, but it was twenty years later before it began to spread in cultivation. It is a

deciduous shrub of spreading, rounded form, with stiff, stout, zigzagged branchlets. It can very readily be grafted on the Virginian Witch Hazel.

A Handsome Late Spiræa.—Among the late-flowering, shrubby *Spiræas*, *S. Aitchisoni* must be given a foremost place, for it is an exceedingly elegant species, a reliable bloomer and quite hardy. This shrub was introduced rather more than twenty years ago, its native habitat being Afghanistan and Northern India. It makes a spreading, loose-habited bush, some 8ft. to 10ft. in height, with gracefully disposed branches which are a reddish tint when young. The foliage, which is deciduous, is ash-like, or pinnate, each leaf being made up of a dozen or more slightly toothed, narrow leaflets. In August the flower panicles break from the ends of the branches in long sprays of creamy-white. The individual flowers are larger and not so closely clustered as those of many allied species, thus presenting less of that toamy, plume-like effect characteristic of this type of *Spiræa*. *S. Aitchisoni* is a robust and easy doer in almost any cool, good soil and those who have failed with the closely allied and more tender *S. Lindleviana* can take up this species with more confidence of success.

An Uncommon Cotoneaster.—That fine plant *Cotoneaster bullata*, which is still uncommon in gardens, is among the earliest of its genus to afford coloured berries and one of the last to lose them. It forms a spare-habited shrub of a few rather stiff, but slightly arched branches about 8ft. or more in height, these being scantily furnished with crinkled, broadly ovate leaves. The flowers are inconspicuous and soon over, but the fruits which succeed them are the size of small cherries and borne in clusters of considerable size. These begin to change colour about mid-August and ripen to a rich crimson. As birds do not seem so fond of them as they are of many other species, these fruits often hang until mid-winter, thus remaining until after the leaves have fallen. *C. bullata* (also known as *C. moupinensis* var. *floribunda*) is a native of Tibet. It is perfectly hardy and of the easiest culture.

The Coral Shrub. The twining evergreen shrub, *Berberidopsis corallina*, is a native of Chile, and although it was introduced as long ago as 1862 it is still rare in gardens. This is doubtless partly owing to the fact that it is somewhat tender and also because it has proved a sulky, "bad doer" with many. But *B. corallina* is a plant of such unique merits that it is worth any amount of patience. It appears to prefer a cool root run in peaty loam or other vegetable soil and, in such, it has been known to do well against a north wall, after refusing to prosper in a southern aspect. The foliage of *B. corallina* suggests a relationship with the Barberry, for the ovate leaves are crisp and leathery and slightly spiny at the margins. The flowers are produced in clusters, each one hanging on a slender, bright red, 2in. stalk like that of a *Fuchsia*. The blossoms, which often remain a long time in the bud stage, open in August to a width of about ½in. and they are a bold coral red which is very effective against the pale green of the foliage. *B. corallina* is a wall shrub that fully merits a good trial in any of our more genial counties. It is said to dislike lime, but opinions do not always agree on that point.

A Little Known Pæony.—Although we have some good hardy plants from Corsica and the Balearic Isles, not every one is trustworthy in our land and at first we are cautious regarding them. Happily the April-flowering *Pæonia Cambessedessii* appreciates our climate and not only flourishes, but grants us its benison of flower with reasonable freedom. It is a very charming species, coming with

red foliage, which becomes green about the time the flowers open. These are single, of a good size and of a beautiful pink, on a plant about a foot or a little more in height. The leaves pass off red also. It is one of the prettiest of the *Pæonia* species and appears to be quite hardy and thriving well. It can be seen doing well on sloping banks of light, gravelly soil. Its seedlings are sometimes said to be tender, but old plants do not reveal any trace of want of hardiness.

Stuartia Malachodendron.—This shrub is one of the most beautiful members of that wonderful flora of the South-Eastern United States to which the attractiveness of our gardens is so largely due. It was first grown in this country by Mark Catesby, whom bibliophiles know as the author of a fine "Natural History of Carolina," and who flowered it in his garden at Fulham in 1742. At present it is one of the rarest of American shrubs. The largest example known (it is about 18 feet high) is in a garden at Stoke Poges. The flowers expand in July and August, and are 2½ inches to 3½ inches across, the five petals pure white, in contrast with which the beauty of the stamens—which have purple filaments and bluish anthers—is most effectively brought out. It is to be feared we do not thoroughly understand the cultivation of this *Stuartia*; either that, or the possibility that it is naturally short-lived, must be held to explain its rarity. But it is clear that it abhors dryness at the root, that it loves a peaty soil, and that it needs a sheltered position. It occurs wild in woods, and will probably be found to succeed best in company with smaller shrubs that shade the ground about its roots—under conditions, in fact, that suit *Euryphia cordifolia*.

Trial of Materials for Grease Banding.—The Royal Horticultural Society will carry out a trial of materials for grease banding in its experimental gardens at Wisley during the coming season. Materials for the trial are invited and should reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey (from whom the necessary entry forms may be obtained), on or before September 15, 1923. (Goods to Horsley Station, Southern Railway).

General Bulbgrowers' Society of Haarlem (Holland).—The various floral committees have recently made the following awards. **FIRST CLASS CERTIFICATE.**—*Iris hispanica* Leviathan, dark golden yellow. **AWARDS OF MERIT.**—*Delphinium Johan*, indigo blue, centre mauve, eye white, symmetrical spike with big single flowers. *D. Lady Astor*, soft rose mauve, self-coloured, small, compact spike. *D. Mrs. Willy van Egmond*, turquoise blue, shaded pink, eye white, flowers semi-double, spike light and elegant. *Iris Niphium Bianca*, nearly white with violet shading, small yellow blotch. *I. X. Blue Giant*, standards purple, falls lavender blue, small and round with yellow blotch. *Papaver orientale* *Wilhelmina Regina*, salmon pink, very large flowers. *Ranunculus asiaticus* *superbissimus* (French *Ranunculus*) *Mahony*, dark brownish red, big flowers, long stems.

THE PRIMULAS OF EUROPE

With Botanical Classification, Descriptions, and
Cultural Instructions

By JOHN MACWATT, M.B.

Crown 8vo., Cloth, 12/6 net; Postage 9d. extra.

The aim of the author has been to produce a handbook that will assist in the identification of those species of the genus *Primula* which are native to the European continent, and at the same time furnish practical guidance to the cultivation of such of them as have been introduced to our gardens where conditions differ so widely from those prevailing in their natural habitats.

Dr. MACWATT is an acknowledged authority on *Primulas*, and his book presents in a concise and interesting manner the results of many years of close personal observation and experience.

ALFRED EDWARDS, F.R.H.S., Fordham, ELY.

DOBBIE'S SCOTCH-GROWN ROSES

are **NOT** propagated cheaply on the unsatisfactory Manetti Stock, nor are they budded on the ordinary Dog Briar so liable to the scourge of mildew, but on a Stock proved over many years to be the best. It is earlier and hardier than the Briar, and in itself, absolutely free from mildew. Growers should get the best even if prices for quality are slightly higher.

CATALOGUE ON APPLICATION.

DOBBIE & CO., LTD., The Nurseries, EDINBURGH

ESTABLISHED 1830.

The "PERFECTOR" ARCH forms an ideal setting for the Rose Garden. The man whose pride is in his Garden will appreciate the simplicity and effectiveness of this design. The construction is light, yet strong enough for a permanency, being specially designed for the cultivation of climbing Roses, Clematis, etc. It is made entirely of OAK and treated with Solignum, size 7 ft. high above ground level, and 3 ft. 4 in. wide inside. Price £1 each. Orders for three or more will be sent Carriage Paid. Cash with order. These can be made wider than 3 ft. 4 in. if required, prices for which will be quoted on application, stating number required.

THE
"PERFECTOR" PERGOLA.

This is constructed with the above Arches spaced any distance up to 6 ft. apart. The longitudinal and secondary cross bars to complete the Pergola are supplied in OAK, treated with Solignum, at 1/6 per foot run of Pergola; any lengths to suit your requirements. Thus the price of the Pergola illustrated, 25 ft. long, works out as follows:—

4 Arches at £1 each ..	£4 0 0
25 ft. run Top Bar at 1/6 ..	£1 17 6
CARRIAGE PAID ..	£5 17 6

State nearest Railway Station when ordering.

Notes from Maidstone.

BUYING A HORSE.

It would be very difficult to buy a horse from a catalogue. One might be cheap at £500 and another dear at £5.

In a less degree the same applies to plants, price and value not being synonyms. A personal comparison not being always possible, therefore one falls back on the reputation of the seller, and if an English firm one has a certain qualification in knowing one's malisons, if necessary, will not be read as benisons.

No. 2703.—VOL. LXXXVII.]

[SEPTEMBER 8, 1923.]

SHRUBS AND TREES WITH HANDSOME FRUITS

THE cultivation of shrubs and trees principally for the effect which they produce in autumn is far more common than it used to be, but even to-day there are many gardens which are sadly lacking both in the gorgeous leaf colouring which, with some species, precedes the fall and in the immense variety of ornamental fruits which should provide beautiful colour effects from early autumn until far into the winter.

For the small garden it is very desirable, whenever possible, to "kill two birds with one stone."

Those shrubs and trees, therefore, will as a general rule have preference which have other features of interest beside delightful autumn tints or admirable fruits. Leaf-colouring is outside the scope of these notes, but as regards ornamental fruiting kinds, additional use may be afforded in a variety of ways. Most obviously, perhaps, the blossoms may be ornamental: this is decidedly the case with many of the Thorns, with *Skimmia*, with *Ligustrum sinense*, with the Crabs, with the Strawberry Trees (*Arbutus*), with many *Barberis*, with the *Mezereon* (which, however, would be more valuable if its fruits ripened later), with *Pernettya*, with many *Rose* species, a number of *Rubi* and the *Leycesteria*.

It is obviously advantageous if the berry-bearer is evergreen, and here the *Hollies* leap to mind, but it must not be forgotten that not all *Hollies* bear fruits. There are some excellent evergreen *Cotoneasters*, the *Pernettyas* are evergreen and so are some of the *Barberis*, though such are by no means the most effective when in fruit. The *Ivies* when they reach the adult stage are very pleasing—even showy under certain conditions of lighting. The *Butcher's Brooms*, too, are effective evergreens with handsome fruits, but *Ruscus* is unisexual, and care should be taken to plant both male and female plants.

Some species are notable both for handsome fruits and fine autumnal leaf-colouring. This is true of the always beautiful Japanese *Acer palmatum*, handsome in bark and foliage, effective when in flower and when hung with its showy "keys,"

and again when, before the fall, its foliage turns a lurid red. *Berberis Thunbergii*, mainly grown for its autumnal leaf-colouring, is effective also with its sealing-wax red fruit, and the same may be said of *Berberis vulgaris* and *B. Wilsonæ*. Most of the Thorns colour delightfully, so do the Spindle Trees (*Euonymus*). *Rhus glabra* and *R. trichocarpa* are noteworthy alike for the remarkable fruit pyramids and the splendour of their autumn garb; while with some of the *Cotoneasters*—notably with *C. horizontalis*—the colouring of the leaf detracts to some extent from the

effectiveness of the innumerable berries. *Beech* and *Hickory* are alike notable as beautiful trees which are attractive when in fruit. The several species of *Hickory* are quite hardy, but should be planted in their permanent quarters from pots when still quite small.

Many of the coral and red-fruited *Barberis* are so beautiful in winter with their slender growth and golden spines that they would doubtless be grown even though they seldom fruited. The very best of these fruiting *Barberis* include *Wilsonæ*, *subcaulialata*, *brevipaniculata*, *Prattii*, *dictyophylla*, *polyantha*, *Sieboldii*, *sinensis*, *Stapfiana*, *yunnanensis* (valuable also for autumn leaf colour) and, last but by no means least, our native *B. vulgaris*. We have in this list plants of all sizes, from the rott. tall *B. vulgaris* to the almost prostrate *B. Wilsonæ*.

The *Cratægus* family is a large one, and most of the species bear ornamental fruits, but some are distinctly more palatable to birds than others, and, quite apart from this, the fruits of some species remain much longer on the trees than the average. The kind illustrated on page 462, *C. stipulosa*, is a Mexican species and remarkable on that account, for few trees from that country are hardy in Britain. It is June flowering and the blossoms are effective. The fruits, which are large ($\frac{1}{2}$ in. by $\frac{1}{2}$ in.), are yellowish and, as the illustration shews, marked with dots. They are retained on the tree for a long period, and are accompanied by the leaves, which, at any rate in the South, persist into the New Year.

The Cocks-pur Thorn, *Cratægus Crus-galli*, is even more effective than *stipulosa*, since its fruits are equally lasting and deep red in colour. This is a handsome species when in flower and remarkable for its brilliant autumnal leaf colour. The Washington Thorn, *Cratægus cordata*, illustrated here, flowers in July and is very distinct. The fruits are very brightly coloured and long lasting. *Cratægus Carnei* is a hybrid of which the seed parent is said to be *C. stipulosa*, but the speckled fruits are orange red; the blossoms, too, are larger and more striking than

THE BRIGHT FRUITS OF *CRATÆGUS CORDATA* REMAIN LONG ON THE BRANCHES.

those of *C. mollis*, the fruit peels on the tree and is much whiter.

C. mollis is a climber, which grows into a tree of some 20 to 25 ft. tall and spreading. It has quantities of small fruits. *C. mollis* is even larger, reaching 30 ft. or even to 40 ft. This is one of the most beautiful of flowering Theae, but the large fruits fall early in autumn.

Crataegus Korolkowii, often known as *C. tatarica* in gardens, also forms a large tree, with exceedingly large and handsome red fruits marked with dots. *C. tomentosa* has dull orange-coloured fruits, but the foliage colours excellently and the tree is very handsome when in flower. *C. macrantha* is remarkable for the size of its thorns and also for its handsome crimson fruits. Other kinds of special merit as fruiting trees are *C. orientalis*, *punctata* (a large grower) and *prunifolia*. The last named, however, sheds its fruit early.

If the number of the true Thorns (*Crataegi*) is bewildering, the *Cotoneasters* are almost as numerous and quite as difficult to select, since here we have quite dwarf shrubs as well as those of moderate stature and at least one (*frigida*) which forms a small tree. *Cotoneaster frigida*, though it is often thus seen on a 6 ft. or 8 ft. leg and is especially effective so trained for a small garden, grows naturally into a spreading shrub up to 15 ft. or 20 ft. high and more through. The foliage is large (3 ins. to 5 ins. long) but not specially conspicuous, nor is the tree when in flower particularly attractive, but when the hawthorn-like "berries" ripen in fairly early autumn the effect is marvellously beautiful. Unless taken by birds the fruits remain on the branches until the new growth develops in spring, when the contrast of the fresh green foliage and the crimson bunches of fruits is very remarkable. Allied to *C. frigida* are *C. bacillaris* and *affinis*. *C. bacillaris* is a most effective large-flowering shrub, but as far as its blackish purple fruits go is much less ornamental than *C. frigida*. *C. affinis* seems to be an intermediate form between *C. frigida* and *C. bacillaris*. It is less attractive than either.

Simonsii is probably the best known of the *Cotoneasters*, growing 8 ft. tall or more. It is rather an upright grower until it has attained some size, when it becomes more spreading. It may be used to make an effective informal hedge or screen, and has even been planted as undergrowth and cut for peesticks, for which purpose the rather sail-like twiggy branches are admirably adapted. The berries are scarlet and the plant is semi-evergreen. *C. acutifolia* is not very dissimilar, though rather smaller in growth, more slender in habit, and the fruits ultimately turn black. It is not a species one would include in a small collection.

In *Cotoneaster Francheti* we have a valuable evergreen species which grows up to 10 ft. tall, with slender, arching, wand-like branches covered when young with greyish brown wool. The foliage is comparatively small and neat and felted beneath, and the blossoms, which (as very usual in *Cotoneaster*) are white inside and rosy without, rather "set off" the tree. The orange-scarlet berries are freely produced, but would be more striking were it not for the greyish down which smothered them. *C. pinnosa* is an allied species of very similar appearance in many ways, but with crimson fruits and pure white blossoms. Though not brilliant, both these species form interesting, useful and attractive shrubs.

Cotoneaster banyana might be described as a giant form of *C. ovata* (known evergreen *C. microphylla*). It is a tree or shrub, a height of 10 ft. and is very useful for a permanent screen. The berries are red and not specially conspicuous, though attractive on close examination.

(To be continued)

CRATAEGUS STIPULACEA WITH LARGE YELLOWISH FRUITS, HAILS FROM MEXICO.

ROSES FOR SCOTTISH GARDENS

ABOUT twenty-three, or possibly twenty-five, years ago I read an article under this same title, and have never been able to suppress a feeling of resentment against its writer because the gist of his article was that it was futile to expect fine blooms of the really good Roses in Scotland, and that only the hardest and coarsest of the old type of Hybrid Perpetuals, the old Damask, Cabbage and Moss Roses, with a few climbers, such as Gloire de Dijon, Seven Sisters and the Ayrshire Ramblers, could be depended upon in the majority of Scottish gardens.

Many times since then I have read similar statements and views and have wondered whether their authors have really seen Roses grown by some of our Scottish enthusiasts; whether they have visited the fine Rose shows at Dunfermline, Dundee, and at Edinburgh and Glasgow, or have visited the Rose nurseries of the Fergusons at Dunfermline, Dobbies at Portobello, Crolls at Dundee, and Cockers as far north as Aberdeen. A fortnight in Scotland in company with some horticulturist who knows his way about, would suffice to disillusion anyone who holds the notion that Scotland is a poor Rose country; and for the matter of that it has been the common occurrence for the Northern growers to swoop down upon the Southerners at the National Rose Society's autumn shows and triumph over them. Yes, my English readers, Scotland has some Roses, and good Roses, too!

It would, truth to tell, be a more laborious task than I should care to undertake to compile a list of the varieties that will thrive in Scotland; for, as a matter of fact, in many gardens, especially on the western side of the country, even the Teas, which are reputed to be least hardy, thrive as one seldom sees them in the average English garden.

The Hybrid Perpetuals certainly do remarkably well, and it is worthy of note that the dark varieties of full substance, such as Charles Lefebvre, Victor Hugo, Xavier Olibo and Prince Camille de Rohan, throw finer-coloured flowers in the cooler Northern climate than in the greater heat of the English summer.

Ulrich Brunner, Frau Karl Druschki, General Jacqueminot and Mrs. John Laing grow with fine vigour and bloom so continuously and freely as to substantiate their claim to the term Perpetuals; and one may see in many a humble cottage garden in Scotland superb blooms of that great and grand old Rose *Her Majesty*, a typical specimen of which is still a Rose "to raise one's hat to."

The Scottish love for a flower of form still savours of the discriminating taste of the old florist, and the best of the old H.P. class are still beloved and grown, bushes of great age and huge size being by no means uncommon.

Of the modern race of Hybrid Teas a large proportion will thrive quite satisfactorily in Scotland, but in view of the fact that the soil is very largely of a light, porous nature and that the seasons are considerably later than in the Midlands and Southern Counties of England, the prudent Scot pays careful attention to the matter of stocks on which Roses are budded, and that, if my observation has guided me aright, is a far more potent factor than even the individual peculiarities of the varieties of Roses themselves.

For a long time my firm conviction was that the cutting Briar (*canina*) was the stock for heavy, cold soils, the seedling Briar for lighter and drier soils, and Manetti for the Teas and Noisettes. That conviction was the outcome of tuition during apprenticeship rather than of personal observation and experience; but when first the laxa stock

began to claim the close attention of rosarians and its use was advocated in the Press, my impression was that 'twas but the whim of a few who always seem to hanker after the new to the detriment of the old and proven. Nothing, thought I, should shake my faith in *canina* stock. A visit to Messrs. Cocker's nursery at Aberdeen opened my eyes to the real merits of laxa stock, for there in that northern nursery, in an exposed field where the winds were both strong and cold, a whole range of modern varieties of Roses was budded on laxa stock, and the evidence was striking and convincing that not only was growth appreciably earlier than in the case of the same varieties on *canina*, but the branches were stouter, the foliage finer and more substantial, and—a great point for consideration in Scotland—the plants on laxa were earliest to bloom. On another occasion I saw, at Messrs. Dobbie's grounds at Portobello,

There are Roses which in England suffer considerably from scorching and bleaching during midsummer's sun. These sorts may generally be relied upon to throw some splendid blooms in Scottish gardens. I have never seen *Sunburst* in a Southern English garden so really fine as it may often be seen in Scotland. The *Lyon Rose* is frequently of indifferent colour in English gardens, but I have seen it very fine in Scotland. *Edward Mawley*, the great flower that is grand when it comes good, is all the better for the extra time it takes to develop in the cooler atmosphere of a Scottish garden; and that lovely tinted Rose *Mrs. David McKee* deserves mention, for the flowers are fine in form and bewitching in colour, where it can open without undue hurry.

If one glances through selections made by English growers of the best garden varieties for amateurs, he will rarely find it necessary to strike

ROSE ALBERIC BARBIER—ONE OF THE BEST RAMBLERS FOR NORTH BRITAIN.

a long border in which many varieties were growing on laxa stock beside the same varieties on *canina*, and the difference in the growth and freedom of the plants was almost uniformly in favour of the laxa stock. Thus was my prejudice against the rival of my favourite *canina* stock broken down, and with a clearer vision I convinced myself that, if one would succeed with the Hybrid Teas, which in many cases are prone to produce too much soft, sappy wood in autumn to be advantageous in Scotland, one should rely upon plants budded on laxa, which makes earlier growth and ripens it earlier than the *canina* stock. Even so good an autumn-flowering Rose as *La Tosca* will ripen up well before winter on the laxa stock, and that means much to the Northern grower.

The value of a late autumn-flowering Rose is not so great in Scotland as it is in Southern England: first, because all Roses are definitely later, the month of September being to Scotland what July is to the Southern rosarian; and secondly, there is the difficulty already referred to of having late bloomers in full soft growth when we want the bushes to be ripening off and losing their foliage.

out one as being unsuitable for Scottish gardens. Caroline Testout and General McArthur are practically sure to figure in the selection, and they are both excellent for Scottish gardens. *Grüss an Teplitz* is a variety well-nigh everybody recommends, and often it is advised that the strong-growing branches should be pegged down. That is very excellent advice, and for my part I would strongly urge that wherever a garden in Scotland is on the hillside, or in an open, exposed situation, it is wisest to grow varieties that can be pegged down. They are much safer and less liable to be blown out of their sockets than when growing erect.

We may peg down Frau Karl Druschki, Gustave Regis (a delightful and altogether charming old Rose), Mme. Isaac Pereire, Duke of Edinburgh (particularly useful for the brilliance of its colour), Gloire de Dijon (better thus than even on a wall) and a good many other fine varieties that will produce quantities of blossom.

The Roses to avoid in districts where the rainfall is rather heavy, as it is in some parts of Scotland, are the very big, heavily built sorts, such as

an idea of what they look like in mass formation, and the other, on the back, of a single spike of a "Burns new hybrid Delphinium." Unlike Mr. Samuel, this raiser goes in for light shades and crows that on his own dunghill he has "nearly eliminated the darker shades." He seems rather up against the bee-like centre and says opinion differs very much about "whether the bee adds or detracts from the flower values." My own opinion is that as a rule it adds to the beauty

of a flower and that, as it is such a distinctive feature, in every single bloom it ought to be retained. When doubling is carried to such an extent that no trace of the bee remains, it is overdone. We want as our ideal to *better the Delphinium*, not to make it into a small florist's Ranunculus or a glorified Bachelor's Button or Fair Maids of France. I know Mr. Samuel thinks pure singles are too dainty and deciduous for this present forgetful and rather matter-of-fact world. [J. J.]

extents the glowing orange *Zanthia* show the spacing and graceful pose which distinguish the best primulinus hybrids from all other sections. For the sake of comparison we also reproduce herewith what the Rev. J. Jacob aptly described in 1921 as the "flower-dressed telegraph pole of dutiful Darling." Some of these "telegraph poles" are quite decorative (the variety *Fire Queen*, for example, which, incidentally, is nicely hooded), but they are not typical of *Gladiolus primulinus*. They have, nevertheless, more to recommend them than the large-flowered hooded sorts, many of which should certainly have gone to the rubbish heap, while the better ones might be segregated in an intermediate group as being showier than the primulinus varieties proper and more graceful than the large-flowered.

The good things which are at present coming from America are "ruffled." Some of these belong to the primulinus section; some should go with the intermediates, while a great number are frankly large-flowered. The ruffling finds favour with most people, so perhaps we shall end by expecting wavy petals in a *Gladiolus* just as now we do in a Sweet Pea.

It is rather strange, but hitherto the primulinus hybrids in commerce show little signs of Colvillei blood. Of course, the Colvillei section are normally out of flower before the "primis" begin to open, but that need present no insuperable difficulty to the hybridist, while the similarity in habit and size of flower would seem to make Colvillei and its immediate relatives invaluable either as pollen or seed parents.

The Lemoinei section is another which seems to have evolved out of all recognition. It is,

AMONG THE GLADIOLI

By THE EDITOR.

HERE is no doubt at all that at present the primulinus hybrids are first favourites among Gladioli. All the other sections might almost be included among the "Also ran." I should fancy that this is particularly true in the United States, for many of the new "primulinus" varieties they are sending out would appear to have been raised from flowers which had a primulinus variety "looking on" at pollinating time. Even then I fancy the looker-on must have worn a respirator or something on a par with the spring chicken's goloshes when he soaked his feet in the chicken-broth-that-was-to-be.

Quite seriously though, some of the new primulinus hybrids from "across the pond," if they have primulinus blood, which is highly probable, do not shew it. Not only are they large and rough—disgustingly large and horribly rough—but they have mislaid the hood, which is surely

the most characteristic feature of *Gladiolus primulinus* and its hybrids.

Of the forms which retain the hood only too many are big and coarse, and the hood itself coarse and "floppy." It is to be feared that for the future we shall have largely to fall back upon British and Dutch seedlings for new varieties of good primulinus type. We want more sorts of similar size and quality to *Nydia*, *Woodcote* and *Orange Brilliant*. Even *Alice Tiplady*, unless not too well grown, tends to come too large, and this is bad in two ways. The mere size of blossom destroys the daintiness of the spike directly, while indirectly it spoils it from a decorative standpoint, because the larger flowers come too close together and so lose the airy grace so characteristic of the section.

The pictures which accompany these notes of the salmon pink *Nightingale* and (to a smaller

THE BRILLIANT ORANGE PRIMULINUS GLADIOLUS ZANTHIA.

A CLEAN BUT SOFT SALMON PINK, G. NIGHTINGALE.

indeed, a "hood and side curtains" effect entirely, and might be rather eddily coloured. Childish varieties of the old closely-hooded *Lemnomen*, that were distinct and interesting, but the constant introductions in this section have lost their

SPRING-FLOWERING BULBS FOR WOODLAND AND GRASS

SETTING aside the tribes of *Narcissus*, there is a number of bulbous plants suitable for naturalising in woodland or semi-wild garden which not only possess very special claims for recognition, but which ought to be planted as early as possible. It is proposed to offer a few suggestions here by way of assisting the perplexed amateur towards making a useful selection from the lists which appear with such commendable promptitude as soon as the first hint of autumn invades the garden.

Among the contents of these lists the Dog-tooth Violets (*Erythronium*) should make a strong appeal, since most of them are easy to grow in any average soil that is well drained, while their beauty and peculiar elegance are unquestionable. The cheapest and least fastidious is the European *E. dens-canis*, of which there are several varieties bearing purple or rosy lilac, prettily reflexed flowers in spring. The leaves of this old species are large and egg-shaped and of a delicate emerald green blotched with reddish brown. Some sorts have much larger blossoms than the type and there is a very charming pure white form. *E. dens-canis* will flourish in much drier soils than most others. It soon becomes established, naturalising freely, and is a most reliable bloomer. *E. grandiflorum* (*californicum*), an exquisite little Lily carrying on one stem several ivory yellow blossoms with a ring of orange at the base, can also be strongly recommended. The variety *giganteum*, of the same species, has even larger flowers of the same delicate loveliness and, like the type, a mottled, glossy foliage of singular beauty. The pale yellow *E. americanum* is another that deserves a place in every collection; and then there is *E. revolutum* in various colours. Two outstanding varieties of this are *Johnsoni*, the large-sized blossoms being a clear rose, centred with orange, and *Watsoni* in creamy white, zoned with bright yellow. With the exception of *E. dens-canis*, which enjoys the early spring sunshine, most of the "Dog-tooths" appreciate partial shade, and the American kinds should have a fairly moist soil. Planting should be done early, preferably among thin grass or other light woodland herbage, the bulbs being set at least 3 ins. deep in light soil and about 5 ins. in a heavier medium.

The hardy *Cyclamens* are so chastely beautiful and so admirably suited for planting in cool, leafy places, about old stumps and along the mossy margins of woodland tracks, that no one who has any such spots as these in which to indulge his fancy can overlook them. Though not one of the earliest, *C. repandum* (*vernum*) is among the prettiest, the vivid carmine blossoms being yielded from April to early summer. This species has the ivy-shaped leaves of the popular autumn-flowering *C. neapolitanum* with a "shadow pattern" of silver running through their cabbage-green. Still earlier than *repandum* is the dainty *C. Coum*, whose deep crimson flowers (there is also a white variety) may often be found with the Winter Aconites and Snowdrops. This species can always be recognised by its small, rounded leaves, which are a plain, heavy green unrelieved by any markings, and akin to this is *C. hiemale*, another winter bloomer, with leaves of the same style as those of *Coum*, but mottled with greyish white.

Better known than *C. hiemale* is *C. ibericum*, an early spring bloomer in which the type has pale crimson blossoms with a blotch of richer colour at the base of each segment. The leaves, which appear after the flowers, are kidney-shaped,

often waved at the margins, and their deep green is relieved by a zone of silver. There are several forms of this pretty species, the variety *album* (*Atkinsoni*) with a magenta eye being the most distinct. Then who does not know the fascinating little *C. europæum* of the Alps, which will yield its sweet-scented, deep carmine flowers with the utmost generosity from late spring onward into summer and early autumn, the most lovable as it is the most reliable and easy of its delightful race? Most of these *Cyclamens*, with the exception of the last mentioned, which may be planted 6 ins. deep, should be put in with the upper part of the corms near the surface and, unless the soil is naturally rich in leaf-mould, an annual top-dressing of well matured cow manure, leaf-soil, turf loam and old mortar should be applied. When *C. europæum* does not prosper it may be tried in a bed mainly composed of old mortar and brick rubble intermixed with a little leaf-mould and overlaid with the latter or finely granulated peat moss.

The *Crocuses* and *Colchicums*, like the *Narcissi*, would need a lengthy article to themselves, so one passes on to the *Snowflakes*, which are also among those that demand early planting. The best known of these is *Leucojum vernum*, the Spring Snowflake, an easy, hardy little plant that should never be omitted when naturalising in this way. Good as it is, however, the Spring Snowflake is eclipsed by *L. carpaticum*, whose twin white bells are of more hearty, ample proportions, each segment being adorned with a golden blotch. This variety (or species?) is perfectly hardy; it will thrive in sun or shade, but, like *vernum*, it asks for a year or two for settling down, after which it will be "a joy for ever"—if left undisturbed. The Summer Snowflakes (so called because they always flower in spring?), especially the *Gravetye* variety, are as easy as *vernum*, and well worth a place where their greater height can be accommodated with a suitable carpeting support.

The *Scillas* usually listed for naturalising in woods and other places must be numbered among the indispensables, for, quite apart from that peculiar fascination of theirs which accounts for the popular esteem in which they are held, they are cheap as bulbous things go and most of them are a perfectly safe investment, since they are easy and permanent almost anywhere, mouse-proof and return a handsome dividend by natural increase.

Though the Siberian Squill (*S. sibirica*) is a dainty, inexpressibly charming little plant that will always hold its own, those on the look-out for something more novel in this way may plant *S. bulbocodium* with every confidence in being no less satisfied with the results. This is a deeper blue than the foregoing and an earlier bloomer. There is a lovely flesh pink form of the same species which is well worth the ruinous outlay of sixpence a bulb. The pale blue form of *S. sibirica* known as *S. s. taurica*, also earlier than the type, is good but not very distinct, but *S. s. alba* is very dainty and refined, and most effective in little clusters among the blues.

For flowering in May there are few plants of the kind under discussion here which will produce such splendid drifts of colour for a comparatively small sum as the Spanish and English *Scillas*, or Wood Hyacinths. These are, moreover, perfectly hardy and good-tempered anywhere in sun or shade, light soil or heavy—so long as the drainage is good—and once they are put in the ground no further attention will be asked by them.

GLADIOLUS PRIMULINUS DARLING.

"hood and side curtains" effect entirely, and might be rather eddily coloured. Childish varieties.

Evolution is a fine thing, but who could wish to evolve, say, a polo pony into a Clydesdale? And who, except, apparently, the hybridist, wants to exchange the *Nydias* and Woodcotes of yesteryear for the sort of slightly hooded *Princeps* forms which are being sent out to-day?

for years, if ever. The commonest of these is the blue, or blue-purple, *S. nutans* (festalis), our native wild Hyacinth, often called "Blue-bell," and few people who have shrubberies, woodland gardens, grass orchards and the like will be without some bold groups of this beautiful species. There is at least one rosy pink variety of *S. nutans* which is a pretty and effective plant; but the pick of the bunch is, I think, the creamy white form, *S. n. alba grandiflora*. This is a really lovely thing whose 15in. gracefully arched flower-stems, strung with their large and elegant bells, are surpassingly lovely in the shade of woodland trees.

Though *S. hispanica* (campanulata) often attains a greater height than the above, and while it affords us a very wide selection of good and distinct

Heavenly Blue is still perhaps the most beautiful and, at the same time, most generous in peopling the world about it with its pretty offspring. But *M. botryoides* in a deeper blue, with the lip of each urn-shaped floret set off with a ring of little white teeth, is no less reliable and charming, and this species gives us white and other forms. These *Muscari* enjoy an open situation in any free lawn, but they will do under deciduous trees. The flowering season extends from March to the end of May. The bulbs are best planted in September 3ins. to 4ins. deep, but those of the exquisite little *M. azureum* (*Hyacinthus azureus*), which must not escape mention, need not be more than about half that depth.

The old Star of Bethlehem (*Ornithogalum umbellatum*) can be a tiresome pest in the wrong

place and of the *Chionodoxas*, which include a selection of charming species, varieties and hybrids, most of which are admirably adapted for associating with *Triteleas*, *Snowdrops*, *Muscari*, *Winter Aconites* and the like. The wonderful gentian blues of *C. sardensis* and *Lucilia*, with their shining zones of white, can never be too well known, but in addition to these there are some pure white forms and hybrids in various shades of lilac and pink. All these are very precious, and in most free soils they naturalise with the greatest freedom.

Those who do not relish the savour of garlic may be well advised to let the *Alliums* alone, always excepting one or two, of which *A. neapolitanum* is a notable example, which have "turned down" the family odour. The species mentioned

THE SO-CALLED SUMMER SNOWFLAKE, *LEUCOJUM ÆSTIVUM*.

THE WHITE SPANISH SQUILL, *SCILLA CAMPANULATA ALBA*.

varieties, it lacks the peculiar grace of *S. nutans*. Albeit, this is none the less valuable for all such purposes as those to which the native Hyacinth lends itself, and the quite upright, tapering spikes have a stateliness of their own which is appealing. *S. hispanica* is, moreover, very hardy and robust and a good coloniser, its flowers opening at about the same time as those of *nutans*. Any good list will offer the reader a description of the various fine blues, lavenders, whites, rose pinks and parti-coloured varieties of this accommodating *Scilla*, and I can guarantee a satisfying and cheerful result from wide plantings of any of them.

The Grape and Starch Hyacinths comprise a number of excellent kinds for naturalising in grass or other short herbage, and they are so distinct both in form and colour that they can hold their own in the best of company. The familiar

place, and so can *O. nutans*. But the silvery white stars of both of these may be very effective and useful when naturalised like *Snowdrops* in a safe place where one may never have to dig them up. They will be quite content in shade and flower in the late spring. Hardly less easy, but infinitely more attractive, is *Triteleia uniflora*, which, in any warm, sunny place among other things of an equally refined and nice disposition, will establish itself for ever. Though a native of the Argentine, *T. uniflora* is quite hardy, and its white flowers, on 6in. stems and delicately shaded with a faint blue wash, are delightfully fragrant. The form known as *T. u. violacea* is distinguished by having rather more blue in its three-pointed stars, and each petal is divided down the middle with a conspicuous stripe. These should be included in the smallest bulb order; and no less can

is happily one of the best for naturalising in woodland, and it carries on its 15in. stems fine heads of white flowers. *A. Moly*, with starry blossoms and large golden discs, and *A. Ostrowskianum* in rose may be mentioned as highly desirable, reliable species for the same purpose, but the trade lists offer many more in a variety of colours. Most of these *Alliums* are robust colonisers, they possess the commendable virtue of being cheap, and they flower abundantly from spring onwards.

Fascinating as they are, the *Fritillarias* are not everybody's plants, but of the many species offered, our own *F. Meleagris* is probably the most satisfactory for naturalising in grass. But even this often has a way of disappearing after a season or two unless the soil happens to be to its liking, when it will flourish abundantly. The white variety is the most attractive of those usually

ated, and although it has not yet been satisfied with the treatment we have accorded it, a good many twopeaces will probably be squandered in the hopes of one day fulfilling the desires of this mad and bloodless thing which is so fascinating and so sad.

It is rather surprising to find a country garden which will not, despite careful cultivation, grow *Erantillaria Melegaris* permanently. As a rule it will flourish in open meadowland, in the rock garden or on the edges of woodland. It commonly reproduces itself (if allowed) from self sown seeds, and the white form is generally considered as easy as the more typical coloured varieties. The species is, of course, indigenous and grows wild in quantity in some Oxfordshire meadowland where the loam is rather on the stiff side. Since it flourishes and increases rapidly on the Dutch bulb farms, it would not seem to be fastidious as to soil. *Ed.*

TOMATOES FOR EARLY CROPPING

CULTIVATORS who can command an unlimited amount of fire-heat throughout the winter certainly need not hesitate to grow Tomatoes in the winter months. From plants raised in due course and of suitable varieties a nice crop of fruits may be gathered practically throughout the winter; but I do not wish to deal with them in this note, but rather with the raising and wintering of plants to afford a supply of ripe Tomatoes quite six weeks before it is possible to secure them from spring-raised stock. Adequate heat and suitable structures are, coupled with cultural skill, necessary to success. I mention these facts here as quite recently an amateur cultivator told me he was intending to raise a good stock of Tomatoes this autumn, grow them through the winter and reap an early harvest of fruits. This was to be accomplished without any artificial heat in his structure, in which very good crops have been grown in the summer months. His astonishment was great when told that in our climate it could not be done.

The seeds should be sown late in September in the northern counties and about October 10 in the southern. The resultant seedlings must be pricked out singly in small pots, the latter filled with lumpy loam two-thirds and leaf-soil one-third. A very small quantity of old mortar rubble may be added, but no organic manure.

The chief point is to keep the plants on shelves near the roof glass to ensure sturdy growth. Before the pots become too full of roots the plants must be shifted to cin. pots; it does not matter when this work is done provided there is no frost at the time, and, furthermore, it is advisable to leave the pots, soil and plants in the same house, doing the actual repotting there too. In these cin. pots the plants must remain till that stage is reached when they should be transferred to the fruiting pots—again, ones doing very nicely. All through, the lumpy fibrous loam should form the bulk of the potting compost. The lowest temperature to be quite safe should be 58°; a night temperature of 62° to 65° is desirable when the first truss of flowers opens. Full exposure to light, no direct draughts on to the plants and ample distance apart are essentials to success. Set every fruit by gently tapping the flowers at noon. Top-dress with a mixture of loam, wood-ashes and bone-meal, paying extra attention to watering,

and a good welcome crop of early fruits may be reasonably expected.

The importance of keeping the plants as dwarf and sturdy as possible cannot be exaggerated.

THE ALPINE HOUSE AND ITS CONSTRUCTION

THE alpine house is now becoming one of the regular features of the up-to-date garden and is, in some cases, replacing the more costly greenhouse where artificial heat is required for the preservation of plants during the winter.

There are several ways of housing alpenes. They can be grown in an ordinary greenhouse in pans, providing the house is well ventilated and receives a full share of sunlight. All alpenes need plenty of sun and air, especially in winter. It is advisable to arrange the staging that the pans can be plunged into a mixture of sand and granite chippings, or something similar, to afford good drainage. This treatment helps to keep the plants moist at the roots and simplifies watering in summer.

A more elaborate way of growing alpenes under glass is to build a miniature rockery in the greenhouse, which is more interesting and gives the plants a more natural setting. As I have just completed the construction of such a rockery under glass, I will relate the chief points which were taken into consideration.

First of all, the position, facing south and south-west, with a blank wall of an outbuilding, was agreed upon. The wall gave good support to the main part of the rockery, which was built with a bold effect nearly up to the roof. Enough room was left to grow plants of a succulent nature,

and the seeds should be sown very thinly and pricking off be carried out in good time, while no effort be spared to keep clean the roof glass.

GEORGE GARNER.

as it would naturally be on the dry side and rather difficult to water. The rest of the rockery was laid out with large bays, so that as many plants as possible could be accommodated.

The soil used for the construction of the rockery was the sittings from a stone quarry, which affords good drainage. The foundation and floor to a depth of 2 ft. consisted of clinker and ashes, which also provide good drainage. The path is rough stone paved, with places left at sides for moisture and shade-loving plants, such as *Primulas*. The whole of the rockery was then top-dressed with at least 1 run. of good soil, to which was added a good portion of sand and granite chippings, so that good drainage was assured throughout the whole structure.

One portion of the rockery is confined to choice plants in pans plunged up to the rims, another to plants permanently planted, and yet another to plants flowering or about to flower in pots completely plunged, which can be changed as the plants cease to flower. This gives a varying interest to the house which would not exist if all the planting were permanent.

The approximate size of the house is 12 ft. high, 15 ft. long and 12 ft. wide, and it contains quite a hundred different varieties of alpine plants. From the point of view of a lover of alpenes, how could space under glass be better employed?

Oxtd.

R. C. JOLIFFE.

THE NEWLY CONVERTED ALPINE HOUSE AT OXTED PLACE.

CORRESPONDENCE

PLANT NAMES.

REFERRING to "Somers'" note on page 444, may I submit that the name Bergamot seems to have been appropriated to *Monarda fistulosa*, L.? In the "Kew Hand List" the genus *Monarda* receives the English name of Horsemint, which in Prior's "Popular Names of British Plants" is assigned to *Mentha sylvestris*, L., and on turning to that species in the "Kew Hand List" I find the name Horsemint given to it as well as to *Monarda*. This is a fair example of the hopelessness of attaining precision in the use of English names of plants. Popular usage will always vary in one district from that in another. The English Bluebell, *Scilla nutans* Sm., must ever be distinct from the Scottish Bluebell, *Campanula rotundifolia* L. In "The English Flower Garden" Mr. William Robinson uses the name Horse Balm to indicate the genus *Monarda*, and that of Wild Bergamot for *M. fistulosa*, agreeing in the latter respect with Prior, who does not give Horse Balm at all. For *M. didyma* the "Kew Hand List" supplies the English name of Oswego Tea, while Mr. Robinson adds the synonym Bee Balm. It may be noted that the origin of the name Bergamot is very remote from the herb *Monarda*. It was first applied to a small, highly flavoured Pear—Bergamotta—grown at Bergamo in Lombardy, and later to the Sweet Lime, *Citrus Limetta*, producing the fruit from the rind of which is extracted the aromatic oil used in perfumery. The herb *Monarda* earned its English title through a similarity in its odour to the said oil.—HERBERT MAXWELL, *Monreith*.

THE CULTIVATION OF STRAW-BERRIES.

I AM induced by another season's experience and by Mr. Copley's article (page 442) again to write a few words on this subject. Mr. Copley says "runners should be taken from one year old plants." Presumably he means ordinary plants that have fruited once, and here lies the chief difference between my methods and his. I was taken to task, with a flavour of contempt, some while ago by a correspondent for maintaining that runners taken from maiden plants, *i.e.*, one year old plants not allowed to fruit, give markedly better results than runners from fruited plants. I still maintain that the difference is surprising, and my opinion is based on full thirty years' practice by myself and many friends and neighbours who have taken my advice. Runners so taken are stronger, healthier and, what is very important, can be had a fortnight earlier. Plant physiology coincides with what practice proves. If a Strawberry plant is forcibly prevented from propagating itself by the seed of its fruit, it naturally makes a strong push to propagate itself in another way. Here, this season, we have had a good object-lesson. By some oversight our maiden plants were too few for our needs and we had to fall back on fruited plants for runners to complete our new bed. We found them scarce, small and fit to plant out only two days ago (August 22), whereas the others were planted the first week in August and are thoroughly established.

I should much like to meet with the growers who, according to Mr. Copley, say "it is a mistake to fruit Strawberries the first year after planting." And here we can afford to smile at his observation that "a small crop of fruit will be borne the first summer after planting." Our first year's crop is invariably (unless the weather defeats Strawberries everywhere) a heavy one and in quality

distinctly the best. Indeed, we regard the Strawberry as an annual, as a great weight of fruit

THE BEAUTIFUL STRAW-YELLOW SEMI-SINGLE ROSE JOANNA BRIDGE.

can be secured from a bed of plants set out only 1 ft. apart every way. We never keep a bed three years, and not always two. But all this depends upon one thing, that is, early planting, by which I mean the last week of July or not later than the first week of August. And this earliness, again, depends upon a supply of runners from maiden plants.

An incidental advantage of this annual system is that the exhaustion of soil consequent on its occupation for three years by the same crop is avoided and Strawberries can come back to it much sooner in rotation. It is well proved that they require fresh ground. I do not think many growers will agree with Mr. Copley that "a light potting compost should be used" for potting the runners. Pure loam and fairly heavy at that is far better, or squares of turf loam where they are obtainable. As to varieties, it is, as with Potatoes and many other things, experience alone which shows what is best suited to each garden. Here, having tried almost every new variety, we find none in the same class as President for richness of flavour, fresh or preserved, and continuance of crop.—G. H. ENGLEHEART, *Dinton, Salisbury*.

ROSE JOANNA BRIDGE.

NO bed of Roses has attracted more attention from hundreds of visitors here than Joanna Bridge (H.F.). We put in thirty plants in the autumn of 1920, and they now stand 5 ft. high and might well be higher, but we have to prune them down somewhat to keep them in good shape. This year they started to bloom on July 1, and are now a solid mass of blooms and buds, which look like continuing until the frosts come. This Rose was put on the market by Mr. Elisha Hicks in 1916, but never seems to have received the praise it merits, although Mr. Hicks has made a strong feature of it at all the important Rose shows.

Its flowers are semi-single, the buds are strawberry tinted, opening to straw-yellow flowers. Where large strong-growing plants are desired as bedding Roses it has no equal, but it must have plenty of room and should never be planted less than

3 ft. apart. We have found it quite immune from disease.—HERBERT L. WETTERN, *Oxford*.

THE JASMINES.

"NORTH WALES," who complains that *Jasminum Beesianum* does not flower, has let his plant grow too tall. It is in reality not so much a climber as a trailer which straggles along the ground, rooting itself every foot or two. But whatever is done to it the flowers never seem to be very large or numerous; moreover, they do not keep their colour well. Has your contributor tried *J. stephanense*, the new pink kind (*Beesianum* × *officinale*)? The old-fashioned single white is, as he says, under a cloud at present, but there are reasons for this. It is a rampant grower; garden walls nowadays are low, and if planted against one of them it takes up an inordinately large amount of lateral room, besides being difficult to manage. Trained against a house it quickly reaches the second storey, and does not flower much until it gets there; the flowers are not large enough to be effective at that height, and if they are to be kept down to the level of the eye a rather troublesome method of pruning has to be resorted to. As regards the double form of *Jasminum officinale* mentioned by "North Wales," will he please indicate from whom it can be obtained?—H. A. BAYNE.

IRIS PRICES.

WITH reference to your correspondent Mr. Long's letter *re* the above, I think he somewhat overlooks the main factors which must determine the price of a commodity such as an Iris plant. The Bearded Iris is rapidly coming to the fore as a "fashionable" flower—thanks to the extensive hybridisation which has been, and still is being, carried on on both sides of the Atlantic and on the Continent. The "supply" of the better varieties will always be the chief

net attention on the price at which these various varieties will sell, which, in turn, will be determined only with the demand but with the rate of increase of these varieties. This latter varies very considerably, as anyone who grows Bearded Irises extensively will readily find out. Again, the "stocks" of certain Irises, some of ten years introduction, are very limited and, for the reasons above stated, growers cannot get their stocks up to a desired level. Though in no way connected with the "trade," I could name quite a few Irises (old ones) listed at prices ranging from 2s. 6d. to 7s. 6d., of which it would be difficult to obtain fifty plants from an individual grower. What is the grower's alternative? It seems to me that he must either (a) continue to sell all he wants of a given variety at his price, or (b) withdraw that variety from his list for a season or two until he has a sufficient stock to meet the demand at a reduced price. This is a matter for the growers themselves, but I should imagine that it is preferable to adopt the former course. As regards Mr. Long's remarks concerning the discrepancy in prices between the Continental raisers and the English growers, the plants sent out by the former at the much lower prices cannot be compared with the plants distributed by our home growers, and in many cases plants from the Continent require "growing on" for a season at least before reaching the flowering stage. Furthermore, I am quite sure that all of our English growers would be delighted to reduce their prices 50 per cent. if they felt that they had any hope of filling the ensuing increased demand.—SIRI.

THE VITALITY OF FOXGLOVE SEED.

AFTER reading the most interesting account of Foxgloves in *THE GARDEN* for July 21, page 373, I thought I would send you a photograph of part of a group taken here, some of them being as much as 7ft. in height. The interest attaching to the picture, however, is afforded by the time the seeds have remained dormant in the ground, while still retaining their germinating power. In the winter of 1906 a large portion of a shrubbery consisting principally of Common Laurel was cut down to within a foot of the ground. It was then dug over, all dead leaves, etc., being dug in. In the following spring patches of Foxglove, Poppy and common Marigold seeds were sown to take off somewhat the bare appearance until the Laurels had grown again. In the summer of 1908 the Foxgloves flowered. By that time the Laurels had grown from 2ft. to 3ft. So, after clearing away the dead flower-stems, no more was thought about the Foxgloves. Now comes the interesting point. During the winter of 1921 we again cut down the same lot of Laurels, repeating the process of digging in the dead leaves, etc. No seeds of any kind were sown. In the spring I noticed something come up thickly all over the ground, which at first sight I took to be weeds, but which proved to be Foxgloves, the seed of which had remained in the ground since the time they were sown in 1908, a period of fourteen years. The photograph gives but a faint idea of what they really looked like, as there must have been between two and three thousand of them of various heights and shades of colour. A few Poppies came up and flowered and one solitary

Marigold, thus shewing that their seeds do not retain vitality like those of the Foxglove.—H. REYNOLDS, *Great Yarmouth*.

LILIUM POMPONIUM.

I HAVE been greatly interested in Mr. Dillistone's very helpful articles on Lily culture, especially on the importance of shading the roots. With almost all Lilies this requirement is beyond dispute, but in the case of *Lilium pomponium*, a native of the Maritime Alps, I do not think it can be necessary, and is probably even injurious. This Lily is locally plentiful in the neighbourhood of St. Martin Vésubie, on very steep limestone hill-sides in the full glare of the scorching southern sun. It is most luxuriant on the low ridges of scree, and very seldom occurs at the bottom of even a shallow gully where small lavender bushes and other dwarf shrubs grow. I noticed that the finest Lilies were always on scree, where there

have found one plant with four flowers and a very few with three on a stem. The colour is almost identical with the more familiar and much taller *L. chalcedonicum*, an intense fiery scarlet of the Turk's cap shape, typical of the Martagon section. Although St. Martin Vésubie is probably the best known locality for this lovely little Lily, it may be found scattered over a wide area of Southern France. It occurs high up on limestone cliffs in many parts of the Var valley and through the Gorge of Daluis as far north as Guillaumes; in fact, its distribution is very similar to that of *Saxifraga lanosecana*, another treasure of the Maritime Alps.—N. G. HADDEN, *West Porlock*.

A VALUABLE ACHILLEA.

IN your issue of April 7, page 176, which, owing to absence from home, had not been noticed before, Mr. Clarence Elliott has a note on an *Achillea* which he calls *A. Lewisii*, saying that

FOXGLOVES FROM SEEDS WHICH HAD LAIN DORMANT FOURTEEN YEARS!

was scarcely any other vegetation, merely a few scattered tufts of grass and a stray *Astragalus* or *Onobrychis*. What the plant evidently delights in is full exposure to sunshine, a light soil rich in lime and the sharpest possible drainage. I do not know if anybody has tried it as a limestone moraine plant, but I feel sure it would succeed well in such a situation, where it would look more at home among small alpine plants than in the herbaceous border with coarser things. The bulbs are usually about oins. below the surface soil, which consists mainly of limestone debris washed down annually from higher ground, but the roots work their way down to a rich loamy subsoil full of stones. Underground watering should not be necessary for *L. pomponium* in cultivation even on a moraine garden, for it certainly cannot obtain much moisture during the summer on the stony slopes where it grows naturally, and the bulbs must receive a thorough baking. In the richer soil of our gardens it will attain a greater stature than it does at home, where it rarely exceeds 18ins. in height and usually bears only one or two flowers. I

"for some reason it has got about under two names," the other being *A. King Edward*. I rather doubt his claim to *Lewisii* being correct by right of priority, as I have known *A. King Edward* for quite sixteen years. This was raised about 1907 from seed saved from *A. tomentosa* in a small garden in North-West Norfolk. Two seedlings came up, one which is known generally in the trade as *King Edward* and the other has not to my knowledge been sent out. It differs from the above in having creamy white ray florets, with a pale lemon yellow centre, the foliage being similar in shape and habit, but lacking the beautiful silvery appearance of *King Edward*. It agrees with it in one respect, that is, in its long season of flowering. The parentage is undoubtedly *A. tomentosa* × *A. ageratifolia*, as these plants were planted close together when seed was saved. The name was decided upon by the raiser and Mr. G. W. Miller of the Clarkson Nurseries, Wisbech, to whom it was given, who about twelve years ago had some at one of the R.H.S. shows at Vincent Square. C. HUBBARD.

HERALDS OF AUTUMN IN A WOODLAND GARDEN

THOUGH the Bracken in the glen is splashed with chrome yellow and amber and the dwarf Furze has added its gold to the purple of the heathery hills beyond the tree-line, I rather think it is the autumn catalogues which flutter in with every breeze that sound the truest knell of summer. For they send one's thoughts forward at a bound to "the moist rich smell of the rotting leaves" and such incidentals as bank balances to which even the wiles of the most seductive of nurserymen must be subservient.

But there are not wanting indications in the garden itself that the "close bosom-friend of the maturing sun" has already set her smouldering fires alight, and one enjoys a feeling of satisfaction rather than regret in the presence of those symptoms of ripeness and fulfilment which fill the poets so often with melancholy. Perhaps this may be accounted for by the fact that August is of all months the least interesting of the average gardener's year, to which September comes as a tonic, stimulating that fresh interest which the advent of another planting season inspires, and which is whetted by the subtle fascination of the said catalogues. Gardeners seem to have been peculiarly susceptible to temptation ever since . . .

But I wander. It was towards *Berberis Thunbergii* that I set out, for no reference to autumn at its earliest can be made without according this species a prominent place. Here this well known, neat-habited shrub is invariably the first to surrender its green and, once it begins to change colour, the transformation is so rapid that in a few days the foliage will be ablaze with that wonderful blend of orange and crimson which makes this familiar

bush so highly valued by all who enjoy autumn tints.

B. dictyophylla also exchanges its emerald for a warm red before most things have prepared to relinquish further claim on summer, and another of the same race which, possibly owing to its being in a very dry spot, flares into crimson at about the same time is *B. virescens*. As for the berrying Barberries, most of them have yet to develop their fruit crop, but the plum-coloured clusters of *B. Darwinii* were cleaned off by the birds before July was out. The berries of *B. Sargentiana*, a shrub more notable for its fine habit, beautiful foliage and coloured bark than for fruit or flower, are beginning to turn black, and the black beads which hang from the arching wands of *B. pruinosa* are getting white with the meal that they will retain all winter.

In *Cotoneasters* the first to show coloured fruits here is *C. bullata*, and this is undoubtedly one of the best, since the berries, borne in large bunches, are fully $\frac{1}{2}$ in. in diameter and a rich blood crimson. They also remain long on the branches, often until some weeks after the leaves have fallen. The prostrate form of *C. horizontalis*, whose fish-bone branches remain on a horizontal plane, in contradistinction to those of the type which are tilted in mill-sail fashion, also colours its fruits early. This is usually a most extraordinary cropper, and a well grown specimen crowded with its brilliant orange-scarlet berries must rank

THE MADRONA, *ARBUTUS MENZIESII*, A SINGULARLY BEAUTIFUL AND OUTSTANDING TREE.

among the very choicest of autumn-fruiting plants.

An old shrub which I always think is most charming between summer and autumn is *Leycesteria formosa*, for it is at this time of year that its smooth, emerald green, hollow canes of the current season's growth are at their freshest and best. Then there are the curious flower clusters, hanging like toy pagodas on a Christmas tree at the ends of the elegantly drooping stems. Though there may still be a few milk-white trumpets at the tips of these strange ornaments, their chief attraction is the wine-coloured bracts which envelop the ripening fruits, presently to turn from crimson to black. These fruits are greedily eaten by birds, presumably after they have fallen, and they germinate so freely that seedling plants appear in all manner of unexpected places.

As its mottled leaves are among the first to disappear, so the vivid scarlet clubs of the wild *Arum* are always to be counted among the heralds of autumn. These afford a pleasing dash of brilliant colour in the green and shady places of one's woodland garden, and they are followed closely by the crimson berries of *Lily of the Valley*, which looks singularly attractive against the creeping Ivy among which the plants that bear them are growing. Though the *Lily of the Valley* does not fruit as freely as one would wish, and though mice or other creatures devour the berries, wisely leaving those of the *Arum* untouched, I am assured that one may be thankful that it fruits at all, this being considered an uncommon occurrence.

The fine golden yellow of such *Hypericum*s as *H. patulum* Henryi and *Moserianum* is just the colour that harmonises most happily with the hues of the coming autumn and there is something to be said at this season for a well grown group of the sub-shrubby native, *H. androsaemum* as an inmate of the wild garden. Though I never feel quite sure that in full summer I like *Fuchsia Riccartoni* as a woodland plant, for it does not seem then to harmonise very happily with anything, its blood red flowers are by no means unwelcome among the warmer tints of the later year. This *Fuchsia* and others are usually at their reddest just when the spikes of many of the Torch Lilies (*Kniphofia*) are ablaze with their brilliant yellows and fierce reds, and among which the medium-sized *K. Nelsoni* may be singled out for very special mention.

Ribes aureum, the Buffalo Currant, changes the pale green of its three-lobed leaves to a beautiful vinous hue before September is far spent, and on that account alone it is worth a place in any woodland garden. At about the same time one may expect the "strawberries" of *Arbutus Unedo* to develop their orange and scarlet tints, which are always so attractive among the pale primrose-coloured flower clusters which arrive with them. Though it has not yet blossomed here, the more beautiful and interesting *A. Menziesii* makes amends for this failing by a process of bark peeling, after which the smooth wood glows with a warm cinnamon brown which is one of the most delightful of the many attributes of merit that can be claimed by this fine species.

On the dry, sunny bank where these *Arbutus* trees flourish, no matter how droughty the summer may be, there are some imposing clumps of *Apera arundinacea*, yet another plant which attains its fullest beauty at this season. The Pheasant-tailed Grass, as it is popularly called, makes an imposing and elegant tuft of narrow-bladed foliage some 2 ft. or more in height and of a pale, shining green suffused with brown. Towards autumn these grass blades assume warm hues of coppery red and rusty vermillion, the green almost entirely vanishing. At the same time the lovely flower panicles slip out of their sheathes and droop over in long, graceful plumes, bronzy purple and soft as silk. The flowering-stems, with their wonderful branching heads, light as air and the very embodiment of elegance, will attain the length of about 3 ft. and last well into the autumn. *A. arundinacea* is, indeed, an all-season plant, for its beautiful foliage is hardly less charming in the depth of winter than it is to-day. Though not quite reliable in severe winters, this species will put up with a deal of cold in a really free and dry soil, and it usually makes sure of the perpetuation of the race by producing plenty of self-sown seedlings.

Some of the *Geranium*s are most conspicuous in the "hectic red" of their passing even before August is out, and not the least beautiful of these in the wilder parts of the garden are our common

Here Robert (or Robertina) and, what might be considered a greatly magnified form of the same, *G. Lowen*. The stout, angular branches of the latter, which bear their rather scanty leaves nearly 3 ft. in height, are a rich blood crimson, and the foliage assumes the same colour as the plant, which is biennial, dies; with no less haste *G. liberum* adorn its foliage with warm tones of crimson scarlet. The *Megaseas* are splashed with red and, also along the woodland walks, one notices that the leaves of *Fiarella cordifolia* are already stained with more than a hint of autumn's flush. What purports to be the variety purpurea

of the last mentioned, always a striking foliage plant, also now enriches the bronzy purple of its handsome leaves, and the curious foliage of *Saxifraga Camp* is enlivened with dashes of carmine.

To all these little indications of autumn's approach the hearty old Figer Lily adds the splendour of its glowing spires. No other flower, not even the *Montbretias*, which naturalise all too freely about the woodland garden slopes, can quench with their fiery orange and vermilion hues that colour note with which the Figer Lily so triumphantly proclaims the passing of one season and the beginning of another. N. W.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Mustard and Cress.—It will now be necessary to use boxes for growing this useful salad and, when the seed is sown, these should be placed in a warm greenhouse. Boxes 3 ins. or 4 ins. deep are suitable and a layer of manure from an old hot-bed may be placed in the bottom, the remaining space being filled with leaf-mould and loam. Do not cover the seeds with soil, but a sheet of paper may be used until germination is effected.

Cabbage.—No time should be lost until the requisite number of plants are set out. The smaller seedlings can be left in the rows until the spring, when they will be found useful to fill up gaps and thereby continue the supply.

Weeds.—These make considerable headway during the present month and, unless they are kept down, it will mean a lot of work later. They rob the soil and retard the crops, so the hoe should be kept busy during the next few weeks. Small gardens often suffer through the neglect of their neighbours who allow their weeds to seed. Some weed seeds are carried by the wind a considerable distance. There are several such patches in my own district.

Endive.—Improved Batavian is a useful variety, and seedlings that are large enough may be planted 15 ins. apart. This is a very good substitute for Lettuce, but it needs careful blanching to be appreciated.

Celery.—At this period of the year every opportunity when the weather is dry should be seized to earth up Celery. Clean the plants of dead leaves, side shoots and weeds, and tie a piece of raffia around each plant before the operation begins. Late-planted Celery must wait a few more weeks before any earthing up is practised.

The Flower Garden.

Crown Imperials.—These old-fashioned flowers are always attractive, and bulbs may be planted from now till the end of October. Other *Fritillarias*, the tuberous varieties of *Iris*, *Sparaxis* and the Dog's-tooth Violets (*Erythronium*) may also be planted. All will thrive in ordinary garden soil, and the last named is suitable for the half-shady rock garden.

Violets.—During the present month these should be transferred to cold frames or heated pits. A layer of rough material should be placed in the bottom to act as drainage, and the rooting medium should consist of three parts loam and one part leaf-mould. Lift the plants with a good ball of soil and get as many specimens in the frames as possible without undue overcrowding. When the planting is completed the foliage should be a few inches from the glass. Give the roots a soaking of water and, until they are established, spray the plants twice daily. The lights will not be required for several weeks unless we get a spell of wet weather. If red spider is present, it will be necessary to syringe the foliage, especially the undersides, with N.L. All insecticide. Pinch out all runners as they appear.

Buddleia variabilis.—This is a shrub well worth growing, being especially valuable for its late-flowering propensities. The best varieties are *Vetchiana* and *magnifica*, and growers should endeavour to keep up a true stock by means of cuttings, which can be inserted in frames during the next few weeks. Seedlings appear freely and, as they are almost invariably much inferior to the kinds mentioned, should be rooted up directly they are seen. In this district they germinate in stone walls, and unless they are removed in the early stages of growth the roots do considerable damage.

The Hardy Fruit Garden.

Planting Fruit Trees. It is time to think about the planting of fruit trees. The order may be sent to the nurseryman and the ground prepared. If a new orchard is contemplated, the stations can be marked and the holes dug out. Standard trees of Apple, Pear, Cherry and Plum should be planted 2 ft. apart, but for pyramid or bush-shaped trees half the distance will be ample. Where Peaches, Nectarines, etc., are to be planted at the base of the wall surrounding the kitchen garden the soil will be good enough for the trees, but it may be necessary to see that the drainage is right, and, furthermore, an application of broken line rubble will be beneficial to all stone fruits. When planting fruit trees the holes must always be large enough to take the roots when spread out to their fullest extent. For orchard trees holes may now be dug 3 ft. to 4 ft. in width and 2 ft. deep, and the soil at the base of the hole should be also broken up. Details on planting will appear later, and although late planting is often practised with good results, I like to finish fruit tree planting before Christmas, hence the reason for making preparations early.

The Selection of Apples.—When making a selection the size of the garden must be taken into consideration and the number of trees required. The object should be to keep up a supply as long as possible, and early varieties must be limited. A few useful sorts are Langley Pippin, St. Everard, Lane's Prince Albert, Cox's Orange Pippin, Bramley's Seedling, Wellington and Stirling Castle. Allington Pippin is considered by some to be a first-rate Apple, but personally I would not recommend it. ["Allington" is not a first-rate dessert Apple, though very handsome, but it is a heavy cropper and is probably the best fruit in existence for that very essential condiment—apple sauce. —Ed.]

Fruits Under Glass.

Strawberries.—Plants that have been placed in their fruiting pots are making progress and the receptacles are filling with roots. At this stage they may be fed with liquid manure about twice each week and, when the weather is fine, a daily spraying of weak soot water will be beneficial. Remove all runners and weeds as they appear, and if the soil has become hard, lightly prick it over with a pointed stick. Expose the plants to full sunshine and keep the roots moist.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.)
Castleford, Chapstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Spring-Sown Onions.—These Onions should now be ready for harvesting. They will in any case firm up more quickly out of the ground than in it if they are arranged thinly on a hard bottom in full sunshine. Allow them to remain in this position for the matter of a fortnight, when they should be graded, tied up in bunches and hung up in a cool, airy structure. The "thick-necks" should be bunched separately and should be used first.

Globe Artichokes.—The crop having now been cleared, the stems should be cut down. Being gross feeders, the plants should receive a good supply of partly decayed farmyard manure, which can either be forked in or be allowed to remain as a mulch until spring. There are two varieties of this vegetable to be met with in gardens; one is somewhat conical in shape and is much inferior to the true Globe variety. It is well to see that one has the real article.

Kidney Beans. As previously advised, any surplus pods of either Dwarf or Runner Beans should be picked before they become tough and be preserved in salt for winter use. It should hardly be necessary to point out that these preserved Beans should be steeped in fresh water for at least twelve hours before being cooked.

General Remarks.—Run the Dutch hoe occasionally between the lines of Winter Onions and Winter Spinach and hand-weed the rows. When clearing off pea straw, store away the stakes in an upright position. Break over the leaves of fully developed Cauliflowers to preserve the whiteness of the curd.

The Hardy Fruit Garden.

Strawberries.—Those who purpose planting strawberries in spring should take runners now, and care should be taken to avoid any that have been produced from blind plants, e.g., those which failed, not merely to set fruit, but to flower, as all such runners are almost certain in their turn to produce blind plants. The plantlets should be run out in nursery lines, the lines 9 ins. apart and the plantlets 2 ins. or rather more apart in the line. Some sandy soil suitable for cuttings should be worked in among the roots. This will facilitate the further production of root and will enable the cultivator to lift the plants with nice little balls at planting-time. Sufficient runners having been secured, the remainder should be cleared away and the plantation be thoroughly cleared of weeds. It being understood that these are one-year old plants, they should receive a light mulching of farmyard manure, to be forked in in spring.

Apples. Some of the earlier cookers will now be available for the kitchen, but unless they are likely to fall, they should only be picked as required. At this early date they soon get soft after being picked. Meantime see that the fruit-room is thoroughly clean and sweetened by the free admission of fresh air. A note should be made of any trees in want of root pruning, of which more a fortnight hence. Rampant growth and failure to fruit or to fruit freely are sure indications that a tree is in want of root pruning.

Loganberries.—The Loganberry and its congeners, such as the Wineberry and the Cut-leaved Bramble, should have the old shoots cut away and the young ones tied neatly up. This applies more especially where the plants are trained on poles or on a single trellis. As I have suggested before, the double trellis is the ideal for training these sprawling Rubi.

Enemies.—Rats, mice, wasps and bluebottles are all apt to work havoc among ripe and ripening wall fruits. The two first mentioned must be kept down either by trapping or poisoning, the last two by trapping with jars or bottles partly filled with semi-putrid fruit, jam and water, or sour ale and sugar.

The Flower Garden.

Carnations.—If plants were layered in July or early August, the layers should now (after being severed from the parent plant) be ready for lifting. On all but very heavy, retentive soils, autumn planting is to be recommended. The bed or border which is to receive them should be deeply dug. Farmyard manure should not be applied, bones in some form being preferable. If some old mortar can be obtained, it will be appreciated by the plants. If the soil is on the light side, it should be trodden firm and the surface be raked smooth. Refrain from treading on it when wet. Lift the plants carefully with the handfork and plant with the trowel about 15 ins. apart.

Violas.—Cuttings should now be plentiful, so that the work of propagation may be undertaken now or at any time within the next few weeks. The cuttings may either be accommodated in boxes and placed in a close shaded frame, or they may be inserted in the body of the frame. I have found that Violas lift with better balls when struck in sifted fibrous loam plus a very small proportion of sharp sand than when struck in the orthodox mixture of loam, leaf-mould and sand in equal proportions. Similar treatment should be accorded to Pansies when they are propagated by cuttings.

Pinks which were propagated by cuttings (often called pipings) should now be planted in their flowering quarters. Seedlings, too, should be planted out if this has not already been done. Although closely allied to the Carnation, the Border Pink is more accommodating than its more pretentious relative. Both the common *alba umbriata* and Mrs. Sinkins are suitable for edgings to walks, and are very effective when so used.

OW READY.

Nearly 250 pages, with Index. Over 40 Illustrations and 8 Coloured Plates.

THE PRIMULAS OF EUROPE

With Botanical Classification, Descriptions, and Cultural Instructions

By JOHN MACWATT, M.B.

Crown 8vo., Cloth, 12/6 net; Postage 9d. extra.

The aim of the author has been to produce a handbook that will assist in the identification of those species of the genus *Primula* which are native to the European continent, and at the same time furnish practical guidance to the cultivation of such of them as have been introduced to our gardens where conditions differ so widely from those prevailing in their natural habitats.

Dr. MACWATT is an acknowledged authority on Primulas, and his book presents in a concise and interesting manner the results of many years of close personal observation and experience.

Published at the Offices of "COUNTRY LIFE," LTD., 20, Tavistock St., Covent Garden, London, W.C.2.

First Advice to Would-be Farmers

THE Book for Allotment-Holders and Smallholders

By F. E. GREEN.

Crown 8vo. 5s. net; by post 5s. 6d.

THIS book throws a flood of light upon those things which everybody wants to know before farming even a few acres. The author discusses sites and markets, the most profitable kinds of Small Farming and the practicability of side-lines and trades created by the new conditions. It is a book of absorbing interest and enormous help to all who wish to make a living from the Land.

Published at the Offices of "Country Life," Ltd., 20, Tavistock Street, Covent Garden, W.C.2.

It's a great feeling—

to have worked hard on the garden and to be covered from head to foot with it! The soil seems to fit as comfortably as a suit of old clothes.

But there's something better still—to be pleasantly clean again when the job is finished. If the signs of honest toil stay on too long they get into the pores of the skin and you feel "stuffy."

KIT will get them out. And not only dirt as thick as you please, but the heaviest blobs of paint, grease or tar. KIT is the magic mover of all things that stick to the skin—the rub-and-a-wipe-and-it's-over soap.

GREENHOUSE AND CONSERVATORY.

Annuals in Pots are very useful for furnishing greenhouse during spring and early summer. Seed of these should be sown from now onwards until the end of the month. After sowing, the seed pans or pots should be stood in a cold frame and there be kept shaded until germination takes place. The seed should be sown thinly and the seedlings be pricked off before they are at all crowded. The pricking off should, in the first instance, be into pans or boxes, from which as soon as they are large enough they should be transplanted to small pots. Some kinds, such as *Schizanthus*, should be grown singly in pots, while slender-growing plants may be grown three or four in a pot. To ensure success, annuals must at all times be grown under perfectly cool conditions, with ample ventilation on all favourable occasions. It is important to keep the young plants well up to the roof glass. A cool, airy greenhouse gives perfect conditions during winter. Although they can be grown perfectly well in cold frames, it is certainly a great advantage if heat is available. *Schizanthus*, *Godetias*, *Clarkias*, *Mignonette*, *Nemesias*, *Rhodanthes* and *Acroclinium* are all useful and popular plants for this purpose. *Scabiosa atropurpurea* in its many beautiful varieties is worthy of more general cultivation under glass, as it is specially useful for a supply of cut flowers.

Housing Chrysanthemums.—Early varieties, where the buds are well forward, should now be taken indoors, otherwise the blossoms are apt to damp. They should be put in a cool, airy house, which should be kept well damped down for a few days, as the plants, until they become accustomed to the different atmospheric conditions, are apt to suffer from the droughty condition of the air normal indoors. Houses should now be cleaned and prepared for the reception of plants that have been stood outdoors for the summer. All plants standing outdoors should be kept well staked and tied to prevent damage by high winds.

***Funkia grandiflora*.**—This beautiful white-flowered, sweet-scented *Funkia* is an excellent plant for the unheated greenhouse. It has handsome flowers and equally handsome foliage, and is worthy of more general cultivation as a pot plant. As it is a strong grower, it requires generous treatment, 7 in. or 8 in. size pots being necessary to do it justice. In the South, at least, it is hardy in warm, dry situations, but it flowers so late that the flowers often get damaged by early frosts.

***Funkia tardiflora*,** a much smaller-growing plant, although quite hardy, flowers very late and is also fine for growing in pots for the greenhouse. Where a stock exists the plants may be lifted from the open at this time and placed in pots. They should be well watered in and stood in a cold frame, where they can be kept close and shaded for a few days until they get established. The variegated varieties of *Funkia lancifolia* and *F. ovata* are also excellent for the greenhouse during spring and early summer. They may be lifted from the open ground during autumn or winter and placed in suitable-sized pots.

***Heeria elegans*.**—This pretty trailing plant is very charming when grown in small baskets. It flowers freely during summer and autumn, and is easily propagated by means of cuttings, which should be put in at this time. One can thus have good plants for making up baskets early in the New Year. For later flowering, stock can again be propagated early in the year. This plant grows quite well in any good potting compost to which a little fibrous peat has been added.

***Helichrysum rupestre*.**—This beautiful silvery-leaved plant is sometimes used in summer bedding schemes. It is not hardy, and well grown plants of it are very charming in the greenhouse or conservatory. Every part of the plant is thickly covered with a thick, woolly tomentum. Like many plants of this class, it is by no means easily propagated, as the cuttings are very apt to damp off. It can, however, be increased at this season and again during the spring. The cutting pots should be stood under bell-glasses in a cool house, taking care they are never too damp. At the same time the cuttings must not be allowed to flag.

Ficus macrophylla is a very useful plant for house decoration or for the greenhouse. For this purpose I consider it superior to *Ficus elastica*, as it is not so heavy in appearance; it also has the advantage of branching naturally, and thus makes a fine specimen where large plants are required. It is easily propagated at any time by means of cuttings, which root readily in a warm case. The more slender-growing shoots are best used for this purpose.

Royal Botanic Gardens, Kew.

J. COULTS.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

**BORDER AND PERPETUAL-FLOWERING CAR-
NATIONS** (A. B.).—The following are splendid varieties in every way, namely: Border—Bookham Clove, crimson; Elizabeth Shifner, orange; Leander, salmon; Lady Hermoine, rich salmon-pink; Cecilia, yellow; and Gloire de Naney, white. Perpetual-flowering—British Triumph, dark crimson; White Pearl and Lady Inverforth, salmon-old-rose.

BEGONIAS FROM SEED (Aber, Caerphilly).—Unless precautions were taken to exclude all insects—even ants—no doubt many of the flowers will have been cross-fertilised in this way. The seedlings from the seed saved may contain an odd one that is superior to the parents, but the majority will not be better, but inferior. Practically all varieties bear pollen; good cultivation being the rule. As the pollen found may be used, but there is no certainty as to quality of resultant flowers from plants raised from the seed saved. Raising new varieties is always an uncertain, but, nevertheless, very interesting occupation, as, sometimes, flowers of high merit result. As the seed pods are ripening, paper bags should be suspended under them to retain them should they become detached, as well as any loose seed.

NARCISSI DISEASED (Narcissus, Cornwall). The bulbs have been destroyed by the eelworm, which has done so much damage to these things in recent years. The treatment consists of heating the bulbs to 110° F., neither more (which would kill the bulbs), nor less (which would not kill the eelworms), for three hours. Narcissi should not be planted in soil from which diseased bulbs have been taken, for the soil is certain to be infected and no treatment that is practicable outdoors can be applied to the soil.

ABOUT CLIMBERS AND BORDER PLANTS ("Barty").—In our correspondent's district (Trowbridge) there should not be any difficulty in getting the following plants soon established on the wire division fence, namely: Honey-suckles, Jasmine, Wistaria and Bridgessia-picata, the last named being very pretty and evergreen. A few small specimens of *Choisya ternata*, *Berberis* and *Skimmia japonica* planted at the foot of the fence and well apart would look charming. The first three named would be quite satisfactory trained on the south and west walls, with, on the south wall, *Rose Aimée Vibert*, white with evergreen foliage. One *Clematis Jackmanni* should be included on the west wall. Add to the list named the following kinds of plants for the border: *Doronicums*, *Anemone japonica* and the white variety; *Dolphins*, *Gaillardias*, *Perennial Asters*; *Phlox*, *Rudbeckias*, *Titomas*, *Achillea* The Pearl, *Lechinis chalcidonica* and the dwarf *Solidago*.

TREES AND SHRUBS.

SOME SUITABLE TREES FOR SHADE (W. F. W.).—One of the best kinds of trees to plant both for shelter and shade is *Cupressus macrocarpa*; erect-growing, rapid, withstands strong winds and always looks well; also, it may be pruned, if necessary. The Purple Sycamore, *Wych Elm* and Common *Acacia* are also excellent. If several specimens of the Almond, *Laburnum*, Purple Beech and Mountain Ash be added, our correspondent would secure a good and interesting shelter to the south side of the lawn. The Fig would be slow in growth and deciduous in winter. A specimen of the Mulberry, in corner position, would give satisfaction, as this tree is generally liked. A selection may be made from the above according to requirements.

OLD ACACIA TREES (A. M.).—There may be a slight smell from the sap or decaying wood of *Acacia* (Robinson) trees. We have never heard, nor can we imagine, that this is harmful in any way. May we suggest that these old trees should have some attention to improve their appearance and prolong their lives. The first work will be to cut off all the dead and dying branches back to living wood, preferably where there are the vigorous young growths spoken of. If there are any holes with decaying wood, these should be cleaned out and tarred when dry. Also tar all wounds made by cutting off branches. To prevent water lodging in holes and crevices creating further decay, these should be filled with cement or large holes with concrete. A dressing of manure from a spent hot-bed, or mushroom bed, will be very beneficial spread over the surface beneath the trees, making a good sweep well beyond the spread of the branches where there are likely to be any roots.

FRUIT GARDEN.

PLUM TREE GUMMING (Folsted).—No doubt, as the tree is on its own roots, the gumming is the result of a too strong growth. The soil must be retained in a firm condition. No manure water or surface mulches of manure must be applied. Care must be taken not to wound any portion of the tree. Dissolve half a pound of common salt in 1 gallon of water and apply to soil over the area occupied by the roots; immediately afterwards pouring on 4 gallons of clear water through a rose watering-can. Do this at once. In November surface dress with a peck of lime.

FRUIT UNDER GLASS.

PEACHES ATTACKED (H. C.).—The Peaches are attacked by a fungus which is causing decay, but this has followed cracking of the skin of the fruit, which is the original cause of the trouble. Probably there has been some irregularity in the water supply. Watering once a week with a solution of 1 oz. of sulphate of potash to the 3-gallon can during May, June and July is an aid to the prevention of cracking.

THE POMEGRANATE (S. A. A.).—This plant is not generally grown in this country, though there is no difficulty in cultivating it successfully, especially near walls

and in the Southern Counties. The small shoots, somewhat similar to those of the Peach tree, should be trained in against the wall, as the flowers are borne on them. Many shoots should be disbudded, if overcrowded, while they are small. The remainder will bear flowers if light and air can reach them. The double-flowered varieties are grafted on the single-flowered stocks. The dwarf variety is usually grown in pots. It flowers freely and lives, with ordinary care—even in small pots—to a great age. The plants require a light but rich loam.

PEACH LEAVES DISEASED (M. H., St. Margaret's-at-Cliffe).—The leaves are affected with the Shot-hole fungus, *Cercospora circumscissa*. The foliage and wood of the tree, the adjacent wall and the ground below should be sprayed with Bordeaux or Burgundy mixture, either of which can be obtained ready mixed. Use a fine nozzle on a good spray syringe and spray at evening or on a cloudy day. The whole plant and foliage must be covered carefully.

BOOK ON PEACH GROWING UNDER GLASS (H. E. G.).—Our correspondent would find either of the two books named below suitable. In the book "How to Grow Vegetables and Fruit for Profit and Exhibition," there are long illustrated chapters on Peaches and Nectarines. This is published by Messrs. Blake and Mackenzie, Islington, Liverpool, post free 1s. 9d. "The Book of the Peach," by H. W. Ward, post free 3s., is to be had from The "C. G. A.," 24-25, St. James's Street, London, S.W.

KITCHEN GARDEN.

CELERY UNSATISFACTORY (J. J. C.).—The Celery is suffering from being a little too dry at some season. There are a few green flies upon it, but not enough to do it serious damage. A dressing of soot will, no doubt, be beneficial to the plants.

CELERY ATTACKED (W. McC., Perthshire).—The Celery appears to have been attacked by green flies which have punctured the leaves and caused the death of portions of them. For these and for the grub which tunnels the leaves, spraying with a nicotine wash is the best remedy.

MISCELLANEOUS.

VEGETABLE REFUSE AND SOIL (H. J.).—Our correspondent should use all the old refuse soil which has been rotting for more than a year. Before applying it to the flower borders, it should be turned over once more and a 5 in. potful of common agricultural salt scattered on every barrow load of the refuse to sweeten it and kill the grubs of injurious insects found there. Lime may be used if salt is not available and, if procurable, add one-third the bulk of farmyard manure also.

YELLOW TREFOIL ON A LAWN (E. T.).—The little yellow Trefoil has spread amazingly this season, but it will doubtless diminish another year and perhaps the grass will grow the better for it having been there, as it so often does after Clover. The best thing to do will be to give the grass a dressing in spring of sulphate of ammonia at the rate of 1 lb. to the square rod of grass, taking care to spread it evenly. This will encourage the grass and check Clover and other non-grass plants on the lawn.

ROSE RUST (Miss J. W. R.).—The rust appears in the form of a yellow dust on the undersides of the leaves, later on developing and forming black dots or patches. The spores germinate freely and thus the disease—a fungus—grows. If the plants are very badly affected root them up and burn them. The formaldehyde may be prepared as our correspondent suggests (one table-spoonful to one gallon of water), and the full strength used in the case of affected bushes; but diluted again by one-third as a preventive. Spray every ten days, three times or so, directly the yellow dust begins to form. As the Roses are standard and weeping standard, prune in the usual way; if they were cut to the ground the stock, only, would grow again, as the budding has, probably, been done in the proper way and the low pruning would result in the loss of the Roses altogether.

NAMES OF PLANTS.—W. S. M.—1, *Leycesteria formosa*, 2, *Perettia mucronata*.—G. H. W., Norwich.—1, *Polygonum sachalinense*; 2, *Daphne Laureola* (Spurge-Laurel).—W. B., Corsham.—*Rudbeckia laciniata* fl. pl. (Golden Glow).—E. A. B., Kings Heath.—*Hydrangea paniculata*.—(G. R. J., Springfield).—1, *Jasione perennis*, 2, *Leycesteria formosa*.—(K. F. S.).—1, *Pinus radiata* (insignis), not very hardy except in favoured positions. 2, *Thuja plicata*; 3, *Cryptomeria japonica*; 4, *Sequoia sempervirens*; 5, *Cupressus Lawsoniana* var. *erecta viridis*. No. 3 should succeed on the Deveron.

NAMES OF FRUIT.—A. T. R., St. Albans.—Apple—Emmett Early. —B. H. J., Essex.—Apple—Emmett Early (Early Victorian).

BUYING A HORSE.

It would be very difficult
to buy a horse from a
catalogue. One might
be cheap at £500 and
another dear at £5.
In a less degree the same
applies to plants, price
and value not being
synonyms. A personal
comparison not being
always possible, therefore
one falls back on the
reputation of the seller,
and if an English firm
one has a certain satis-
faction in knowing one's
malisons, if necessary,
will not be read as
benisons.

Established 1796.

[SEPTEMBER 15, 1923.]

PLANTS FOR THAT HOT BORDER

SOME of the most interesting plants our gardens hold are suitable only for special positions or particular composts, or *very probably* both. There are numbers of plants, to come down from the general to the particular, which love shade and will furnish the shady border; and, again, there is an equally wide selection for the border which is sun-parched, so that there is no excuse at all (except ignorance) for the wilting Phloxes, Michaelmas Daisies, Rndbeckias and such like which one too often sees in such positions.

Among shrubby things we have the Rock Roses (*Cistus*) and their cousins the Sun Roses (*Helianthemum*), both in great and beautiful variety, which are glad of all the sun they can get. Then we have the Spanish Broom (*Spartium junceum*) which will grow in sun or semi-shade, but is not over-hardy and will tolerate poor, dry soil. Shrubs with grey foliage are specially fitted to endure heat and drought, and here the *Santolinas*, *Lavenders*, *Olearias*, *Caryopteris*, *Artemesias*, etc., prove invaluable.

When we come to herbaceous and bulbous plants there is still no shortage, especially in the latter class. All the heat available in these Islands is necessary so to ripen *Crinum Powellii* and its beautiful white form that they will flower satisfactorily. The same applies to the *Belladonna Lily*, *Amaryllis Belladonna*; to the *Regelio-Cyclus* Irises (and the *Oncocyclus* varieties if these are attempted); to *Iris unguicularis* and its several forms; to the *Tigridias*; to the *Calochorti*; to the *Brodieas* and most of the *Alströmerias*. *Habranthus pratensis*, an *Amaryllid* with brilliant scarlet blossoms growing a foot tall or rather more, appears to be quite hardy, but flowers freely only when in a really sun-baked spot.

The *Belladonna Lily* should not only have a warm corner, it should have protection as far as possible from the east. This plant develops its foliage in late autumn and winter, and if this is damaged, as it often is, either by morning sun on frosted leaves, or, to a lesser extent, by wind, the bulb can scarcely be expected to produce flowers the following year.

The *Regelio-cyclus* Irises are admirably suited for a sun-parched position in light soil, but the latter should be enriched with good decayed cow-dung if obtainable, otherwise Wakeley's Hop Manure is an excellent substitute. They should be planted towards the end of October and should be lifted each year after flowering. The presence of lime in the soil is essential for these Irises—a fact which should be remembered at planting-time.

Iris unguicularis, or *I. stylosa* as it is still generally called in gardens, is apt to grow unthrifflly in rich soil, especially if at all moist, and in this condition not only fails to flower, but is in danger of succumbing to winter cold. Quite apart from this and the fact that this charming species never blossoms freely after a wet, cold summer, there are many forms of the plant, and some of those most frequently met with are neither the most beautiful nor the freest to flower.

Tigridias for outdoor cultivation should be kept in sand until March and then planted on a really warm border in good soil. Given favourable weather conditions, they are very effective and attractive in late summer.

The *Calochorti* or *Mariposa Lilies* come mainly from California and, as one would expect, revel in strong sunlight. In most localities a frame set against a south wall has proved most satisfactory for their cultivation, but the enthusiastic hardy plantsman is always keen on growing such things in the open, and a south border in those parts of the country where sunlight is abundant gives fair results in an average season. They must be planted in autumn and given a certain amount of protection through the winter.

The *Brodieas* are hardier than many people suspect, but it is wise to give them a little protection in winter. It is fallacious, too, to suppose that they like a poor soil. On the contrary, they like one in good heart. Hop manure is very useful for these and, indeed, for bulbous plants generally, since it is free from insect pests and less likely to harbour fungoid disease.

All the *Alströmerias*, which may be grown outdoors, save only the hardy and rampant *A. aurantiaca*, like a warm, sheltered border. The many forms of *A. chilensis*, *A. Pelegrina*, *A. psittacina* and *A. versicolor* or, as it is more often listed, *A. peruviana*, include those most satisfactory for culture outdoors.

The Bearded Irises in general, provided the ground is well and deeply worked and plentifully supplied with lime, will tolerate much heat and, indeed, flower the better for it, and

REGELIO-CYCLUS IRIS ARTEMIS, A STUDY IN SHADES OF PURPLE.
The blotches are black and the reticulations on the falls white.

ONE OF THE HANDSOMEST OF THE MARIPOSA LILIES, *CALOCHORTUS MAWEANUS* WITH MAUVE FLOWERS.

AUSTRALIAN PLANTS LIKE HEAT. THE PICTURE SHOWS *ERIGERON MUCRONATUS*

IDEAL FOR A WARM, BUT NOT TOO SUNNY, BORDER, THE ST. BRIGID ANEMONES.

their beautiful foliage adds greatly to the attractiveness of the border. The name of them is legion, and it would be quite inappropriate to enter into a discussion as to their several merits here.

The Californian Poppy, *Romneya Coulteri*, though much harder now than when first introduced, flowers best at any rate in cold summers on a south border. This is one of the plants no garden should be without.

Australian plants are almost without exception sun-lovers, and the ever-blossoming little *Erigeron mucronatus*, illustrated herewith, though not a choice plant, simply revels in sun and heat.

The Anemones of the coronaria and pulgens race, including the beautiful St. Brigid and St. Bavo strains, like a nice warm border it shades available from midday sun. In small gardens such plants are often sought for.

There are a number of annuals, biennials, and perennials which, being neither, are usually renewed annually from seed, which flourish on a really hot border. The amount of drought which a *Sisylastrum* will stand is immense, and the great variety in colour and habit now obtainable is forced upon our notice at every turn. The *Eschscholzia*, surely one of the most showy plants we have, is a great lover of sun and heat, and should be raised from seeds sown in spring or autumn in the place where it is to flower. From white, through cream, soft yellow and various bright yellows or hints to orange and so on to chestnut-brown, there is a wonderful colour range, while many have tones of rose or purplish crimson on the outside of the petals.

The *Geraniums*, or Horn Poppies, also, like a sunny border and, though reckoned perennial, are best renewed from seed. The *Dianthus*, the *Antirrhinums* are excellent for the front of the border, but should not be used too freely, since they are not beautiful when "shattered" up in dull weather. The herb of one of *D. aurantiaca* appeals to most people, but the immense and beautiful colour range of the hybrids is attractive. These run into almost identical tones with the *Gerbera* hybrids. These latter, by the way, will grow outdoors on a really hot south border, but we cannot truly state that they are usually a great success.

How often does one see the wall behind such a border planted with quite unsuitable wall shrubs. Rose Dorothy Perkins is often planted in such a situation, and very unhappy and pest-ridden it looks! If Roses are wanted, there are numbers of Climbing Teas and Hybrid Teas which would succeed, as well as the charming little Banksian Roses. There are so many attractive shrubs which would luxuriate in such a position that there is no need whatever to plant kinds which would thrive out in the open garden. Consider the many beautiful *Ceanothuses*, *Abutilon vitifolium*, the *Carpenteria*, the not very hardy *Jasmines*, such *Clematides* as *Armandi* and the host of other climbers which would grow on a south wall, but may not otherwise be had outdoors, and it becomes evident that common things should find no space there, even if they succeeded, which they very seldom do.

Really tender kinds should, wherever possible, be kept for a wall with an aspect to the west or south, or, if this is impracticable, shade from the morning sun may sometimes be afforded by a projecting chimney-breast or by a buttress of vegetation on trellis-work provided by the gardener. Rare fruiting trees, such as the Loquat and the Pomegranate, are attractive for such places. The former has remarkably handsome foliage and the latter is beautiful when in blossom, so that the plants when they are produced, are in the place of themselves and all the more appreciated for the result.

THE BEARDED IRISES

BY W. R. DYKES, M.A., L.E.S. L.

SOME weeks ago there appeared in these columns an article on Bearded Iris species, which summed up what was known of them about thirty years ago, at the time when Baker compiled his Handbook of the Iridaceæ. The so-called species were described in the order in which they appeared in Baker's book, and in many cases the wording of the descriptions was identical.

Since 1892, however, much research work has been carried out, and our knowledge of the wild species of Iris and of natural and garden hybrids between them has grown very considerably. This growth has been made possible by the examination of the very numerous dried specimens of wild plants which are preserved in the various herbarium collections and by the cultivation of living plants from known localities.

Thus we now know the difference between *I. pumila* and *I. Chamæiris*. The former has practically no stem and a long perianth tube between the ovary and the flower, while the latter has a stem which is at any rate always longer than the tube.

Colour alone is no guide to specific difference, and both these species may have either yellow or purple flowers. The curious thing is that in some localities there is apparently very little colour variation, while in others every plant seems to be different. Thus *I. Chamæiris* on Mount Coudon behind Toulon is all yellow or yellow flushed with brown, while at Roquehaute on the coast of Hérault there is every variation. *I. pumila* in the Deliblat in Hungary is always purple, while on the Geissberg outside Vienna and on the Dahnatian coast near Zara and Sebenico there is infinite variety.

Many of the plants sold as *pumila* are in reality *Chamæiris*, but no one who has once seen the ripe seed-pods of *I. pumila* will ever again confuse the two species. The capsules are literally on the ground, broad at the base and tapering to a conical point to which is still attached the long, withered perianth tube and the remains of the flower. The ripe capsule splits open, not from the apex, as in *I. Chamæiris*, but below the apex, as in *I. arenaria* and in the species of the *Regelia* group.

I. Chamæiris is found only in South-Eastern France and in Northern Italy; *I. pumila* in Austria and Hungary, Croatia, Greece and Southern Russia.

In Sicily there is a rather delicate species like a large *I. Chamæiris*, but with the long tube of *I. pumila*. It looks not unlike a natural hybrid between the two species, but it can hardly be so, because artificial hybrids between them are quite sterile and differ in some slight but well marked details.

For some unknown reason Balkan Irises have sharply keeled spathes—the green or membranous sheaths in which the buds are contained. There are, in fact, quite a number of Balkan species with keeled spathes, which have counterparts in Western or Central Europe, in which the spathes are either shapeless or merely rounded. Thus

I. spuria and *I. graminea* correspond to *I. Sintenisii* and *I. Urmovii*. In the same way the Balkan *I. mellita* and *I. Reichenbachii* correspond to *I. pumila* and *I. Chamæiris*. Of both there are yellow and purple forms, which have been described as distinct species. Thus *serbica* and *bosniaca* are merely yellow forms of *I. Reichenbachii*, while *balkana* and *Athoa* are purple. *I. mellita* is dwarf like *pumila*, but has sharply keeled spathes and is the species of which one variety from Skutari, opposite Constantinople, is in cultivation under the name of *rubromarginata*. *I. Reichenbachii* has a stem from 3 ins. to 6 ins. in height

only what we should expect of plants which are natives of countries like Central Europe with a rigorous winter climate.

I. aphylla has a host of synonyms, such as *biflora*, *bisflorens*, *bohenica*, *hungarica*, *furcata*, etc., some alluding to its habit of flowering a second time in the early autumn, some to the branching habit of the stem, which forks characteristically below the centre, and others to the various localities in which it is found. It is characteristic, also, of *I. aphylla* to have spathes of thin membranous texture either wholly green or more or less flushed with purple. The colour of the flowers is usually a deep purple, though both yellow and almost white forms are not unknown.

I. variegata comes from Hungary, Croatia and the Balkans, and is the source of the yellow colour in our garden Bearded Irises. In the wild plant the standards are yellow and the falls more or less closely veined with some shade of brownish purple on a yellow or creamy ground. The spathes are green and remain persistently so, even when the flowers are fully developed.

In *I. pallida*, on the other hand, they are always wholly scarious or papery, even long before the buds emerge from them. It is interesting to remember that all such plants as *sambucina*, *squalens*, *lurida* and even *germanica* have spathes which are scarious in the upper part and green or herbaceous in the lower part, an indication that they are hybrids which owe their origin to a cross between a species with herbaceous spathes and a species with scarious spathes.

Another fact, which appears only to have come to light in the last ten or fifteen years, is that in the only two localities where *I. variegata* and *I. pallida* are both known to grow wild, namely, near Bozen in the Tyrol and on the Velebit Mountains above Carlopago on the Croatian coast, natural hybrids also occur identical with those to which such names as *squalens* and *sambucina* have been given. In such hybrids it is easy to see the struggle for mastery of the purple of *pallida* and the yellow of *variegata*. Moreover, it is quite easy to raise these hybrids in our gardens by crossing the two species.

I. germanica is frankly a puzzle.

All we know for certain is that it has never been found undoubtedly wild anywhere. Moreover, it is extremely reluctant to set seed under any conditions, and it has a habit of making its new growth in the autumn, which would mean that its foliage would suffer in a Continental winter and the plants remain flowerless, as they not uncommonly do even in this country in a season of late frosts and in exposed situations.

Again, there is not one *germanica* but several. The common form in this country is bluer than those we find in Southern France. The variety *Kharpuz* was sent to Foster from the town of that name in Northern Asia Minor and is naturalised near Srinagar in Kashmir, while *atropurpurea* grows in masses at Beaucaille, opposite Tarascon on the Rhone, and at many other places in the

IRIS VARIEGATA, "THE SOURCE OF THE YELLOW COLOUR IN OUR GARDEN BEARDED IRISES," CONTRASTED WITH IRIS KÖNIG.

and a comparatively short tube. *I. mellita* has a long tube and is nearly always stemless.

These four species, *pumila* and *Chamæiris* in the west and *mellita* and *Reichenbachii* in the Balkans, are never more than a foot in height, and the only other species which are certainly natives of Central Europe seem to be *I. aphylla*, *I. variegata* and *I. pallida*, of all of which there are many local varieties. All those who have grown them know how readily and persistently they all set seeds, while it is comparatively rare to see a pod on any so-called *germanica*, *lurida*, *flavescens* or *sambucina*, and rarer still to find more than one or two seeds in them.

I. aphylla, as its name implies, loses its leaves entirely in autumn; so, too, do *I. variegata* and *I. pallida* to a very large extent. This is

South. Many of the forms found growing abundantly at Lido di St. Andrea in Nèpal a hundred years ago! About 100 years ago I found an Iris growing high up on the rocks between the two arms of Lido di Como, in a position where I felt sure it must be wild and not an escape from cultivation. When the plants, which I brought home, flowered they proved to be Kochii, but, unfortunately, they will not set seed, as we should expect them to do if Kochii were a wild species. No form of germanica has been known to reproduce itself from seed. The few seedlings that have been raised are all dwarf plants, resembling *I. aphylla* more than any other species.

Another puzzle about germanica is that each purple form seems to have a corresponding albino form. The so-called germanica alba is one, another even whiter was found growing by the roadside in Istria, while the well known florentina is another. This is the albino of a slender form of germanica which is used along with pallida in the manufacture of orris root near Florence. Streaks or patches of purple not infrequently occur in flowers of florentina and also in the other albino forms of germanica. Florentina has nothing whatever to do with *I. albicans*, which is the albino of the Arabian *I. Madonna*. *I. albicans* and *I. Madonna* can easily be picked out of a collection in winter by their curiously twisted leaves and by the fact that the tips are always browned by the frost. *Albicans* has been transported all over the world as an ornament for Mohammedan graveyards, while *Madonna* was only discovered in, and introduced from, South-Eastern Arabia less than twenty years ago.

I. pallida has many local forms. Near Bozen it is a sturdy plant 3 ft. high with a stiff stem and very glaucous leaves. In Dalmatia it is much more slender, with either green or glaucous leaves and flowers of every conceivable shade of purple, using that unsatisfactory word in its very widest sense. Ciengialti and Loppio are only two forms among a vast number to be found on the eastern coast of the Adriatic, and the so-called pallida dalmatica is almost certainly of hybrid garden origin and not a native of Dalmatia. It is much nearer to the Bozen form than to anything that grows in Dalmatia. Moreover, it very rarely sets seed and, when it does, gives a long series of variations.

Another old garden plant, *flavescens*, is similarly almost certainly of hybrid origin. It seldom sets seed and is quite distinct from *I. imbricata*, with which it has been confused. The latter is a plant from the south-western shores of the Caspian, and was once grown at Kew under the name of *obtusifolia*. The flowers are of a curious greenish yellow, sometimes streaked with purple, and the spathes are very large, green and inflated. In cultivation a purple-flowered form of it has appeared. Neither *flavescens* nor *imbricata* are found growing wild in the Balkans.

I. kashmiriana is a difficult plant to flower in this country. It wants a thorough roasting in summer, and has a purple counterpart, which seldom finds its way beyond the borders of Kashmir. The white form is used for decorative purposes by the natives, as is also *albicans*, and the purple form is as neglected as *I. Madonna*.

The so-called *plicata* can hardly be a wild species. It does not come true from seed, and it is not known to occur in the wild state anywhere. It seems rather to be a seedling or hybrid of *I. pallida* and is, in fact, a *pallida* in which there is some factor which prevents the purple colour from spreading all over the segments of the flower. The colour is confined to the veins and usually to the extremities of the veins near the circumference of the petals.

In Asia Minor and in the hill country to the north of Mesopotamia there are undoubtedly

several little-known or unknown species of Bearded Iris. Specimens have occasionally been in cultivation, but never apparently for very long, nor has anyone tested their validity as species by raising them from seed. Moreover, the specimens seem always to have come from inhabited areas and not from regions in which it was obvious that they were wild plants. Probably, now that we are once more at peace with Turkey, it will be possible to obtain further specimens and to decide how many species there are.

At present the claims of *I. trojana* to specific rank seem undeniable. It has a tall branching

stem, long, narrow pointed buds and comparatively narrow foliage. It is supposed to have reached the Vienna Botanic Garden from the neighbourhood of Troy, but it is obvious that a plant from such a locality might not necessarily have been a native of it if, as now seems probable, Irises were in cultivation as garden plants when Minos reigned at Cnossus in Crete about 1600 B.C. However, *I. trojana* seeds readily and reproduces itself with those slight variations in the tone of colour in the flower which we expect to find when raising a species from seed. It is probably to *I. trojana* that we owe the tall, branching habit of many of the newer hybrids.

PHLOXES—DWARF AND TALL

THIS family consists of about twenty-seven species, of which nearly all are natives of North America, the only exception being *P. sibirica*, which is found in North-Eastern Asia. Somewhere about a dozen species are, or have been, in cultivation, and these include many popular garden plants, the best known of which are the numerous varieties of *P. paniculata*, or *decussata*, as it is sometimes called. The many beautiful garden forms constitute a prominent feature in gardening, either planted in groups in the herbaceous border, or placed by themselves in beds in half shady situations. These, with *P. maculata* and *P. glaberrima*, form the taller-growing section of the genus. The majority of species are of a dwarfer habit and very free-flowering. These low-growing plants are excellent for ledges and banks in the rock garden, or for a well drained position in front of the herbaceous border. They are charming in spring,

many species forming large cushions of foliage close to the ground, so thickly covered with flowers that the foliage is entirely hidden. Though perfectly hardy, they suffer frequently from damp in winter, so that they naturally require a sunny and well drained position in light, rich soil.

All the dwarf Phloxes are readily increased by cuttings in late summer. These may be taken off when long enough, after the plants have finished flowering. They should be inserted in pots in sandy soil and placed in a close, shady frame for a time, when they will strike freely and form nice pieces ready for planting out in early spring. Unlike the taller kinds they do not take kindly to division. The latter may be increased by division in early spring, or by means of cuttings in the autumn. Old established clumps of the dwarf kinds benefit by a top-dressing of rich soil in the autumn worked in between the trailing branches. All the kinds mentioned below have been, or are now, in cultivation.

P. AMENA.—One of the dwarf species, this is a well known charming plant of prostrate habit, with evergreen hairy leaves and bright rose-coloured flowers, very profusely borne in spring. It has been in cultivation for nearly a century, and is a native of the hills and dry barrens of Virginia and other parts of the United States. A useful, early-flowering plant, valuable for the rock garden, or for spring bedding, it grows freely in any good soil.

P. DIVARICATA.—This is one of the most distinct of the Phloxes, growing 1 ft. to 1 1/2 ins. high, and is worthy of a place in the border or in the rock garden. Like many other kinds, this somewhat frail-looking plant fully appreciates a rich and deep soil, with frequent transplanting, which is best done early in

ONE OF THE BEST FORMS OF PHLOX DIVARICATA—VAR. LAPHAM.

September or in March. The pale blush-lilac flowers are freely produced in branching corymbs during April and May, the corolla lobes being either entire, or notched at the apex. That with the notched lobes is the type, while the other is sometimes called var. *canadensis*. Unlike most of the other dwarf *Phloxes*, it does not last long in flower, but, in spite of that drawback, it is well worth its place in the garden. There are many varieties of this species, one having almost pure white flowers. Var. *Lapham* is a handsome kind, with larger flowers of a richer colour and entire corolla lobes. There are also varieties with flowers of a rosy purple colour, probably garden hybrids. This species inhabits damp woods in Canada and the United States.

P. DOUGLASSII.—This species of *Phlox* is of dwarfer, more compact habit even than those of the *subulata* section, forming tufts of thickly interlaced stems, covered with stiff, slender leaves. It is one of a set of dwarf-growing species found on the Rocky Mountains, which includes *P. caespitosa*, *P. canescens*, *P. bryoides* and *P. Hoodii*, all desirable plants, but not yet all in cultivation. *P. Douglasii* is usually found growing in dry, rocky ground, or on bare mountain summits, and varies considerably in the size and colour of its flowers, ranging from shades of purple to lilac and white. Those with the darker flowers are smaller in habit, with somewhat greener foliage, while in the var. *diffusa* the pale lilac flowers are much larger and borne on plants of a laxer habit. To grow the plant successfully it should be planted in soil of a stony nature with a large flat stone laid over the roots to keep them cool in summer.

P. DRUMMONDII.—This is a well known, half hardy annual from Texas, growing up to 1 ft. in height, with pubescent foliage and corymbs of beautiful flowers, varying in colour from rich rose to purple and white, in August. It should be sown in heat in spring and planted out where it is to flower in May or June.

P. GLABERRIMA is a slender-growing species near *P. ovata*, but taller, with narrow glossy leaves on stems up to 2 ft. high. Its reddish-purple flowers are produced in panicles during July. It is native of the prairies and open woodlands of the Southern United States. *P. g.* var. *suffruticosa* is a more robust form, with rose-coloured flowers.

P. MACULATA is also a slender-growing plant, 2 ft. high, closely allied to *P. paniculata*. It has a narrow panicle of rosy-purple, sweet-scented flowers in July. This species likes a rich moist soil, it being found in rich woodlands and along the banks of streams in the Southern United States. It gets its name from the usually purple-spotted stems.

P. OVATA.—A handsome plant, with somewhat fleshy leaves and smooth stems up to 9 ins. high, bearing corymbs of large, rich, rosy-purple coloured flowers in summer, this species has been in cultivation since the year 1759 and is very hardy, doing well in stronger soil and moister situations than the others. This plant is often grown under the name of *P. carolina*, which is really a variety of this species with taller, hairy stems and smaller flowers, light purple rose in colour and starred in the centre with a darker shade. The latter plant was the first kind of *Phlox* introduced into this country, having been in cultivation since the year 1728. It is a native of South Carolina and is less hardy than the type.

P. PANICULATA. From this species and *P. maculata* have been produced all the popular and beautiful border *Phloxes* usually known under the name of *P. decussata*. The type plant grows up to 5 ft. high or more, according to situation and soil, and bears large panicles of rosy-purple flowers in August. There is also a lovely pure white-flowered variety. Both these are excellent garden

PALE BLUISH LILAC—*PHLOX DIVARICATA CANADENSIS*.

ONE OF THE CHOICEST AND MOST CHARMING SPECIES, *PHLOX DOUGLASSII*.

plants, more graceful and elegant in habit than the shorter, stiffer-growing hybrids. The type is a native of the Southern United States and is usually found growing in open woodlands.

P. PILOSA is a slender-growing species about 1 ft. high, with flat corymbs of purple flowers of large size. *P. p.* var. *oculata* is a charming plant, with white flowers, having a purple eye. Very variable in habit and colour of flowers, *P. pilosa* is found in dry or sandy woods over the whole of the United States.

P. PROCUMBENS.—This is a hybrid between *P. amena* and probably *P. subulata*, of prostrate habit, with lilac flowers, having a darker eye.

P. REFLANS (var. *P. stolonifera*).—A pretty plant of dwarf creeping habit with reddish-purple flowers and suitable for the rock garden. It is very free-flowering, sending up numerous stems

4 ins. to 6 ins. high, about the beginning of May, each bearing about six of its richly coloured flowers. A useful plant for spring bedding, it is easily propagated by its runners, and thrives well in light, rich soil in a partially shady position. It is a native of damp woods in the Alleghany region of the United States.

P. SILLARIA is a native of Southern Illinois, where it is found on the cliffs of the Kentucky river, growing in the fissures of precipitous rocks. It is closely allied to *P. subulata*, but is of more spreading habit, with longer leaves and more scattered flowers. These are very pale blue, or almost white in colour. *P. s.* var. *lilacea* is a charming tree-flowering form, producing an abundance of bloom and lasting for a considerable time in perfection.

P. serotina. The Moss Pink is a prostrate, growing perennial, forming moss-like tufts of rounded foliage, with stiff, pointed leaves. Only one or two inches high, the whole plant is covered in spring with sheets of flowers of various shades of colour. The type has pale purple or flesh coloured blossoms, with a dark purple eye and is a native of

the Eastern United States, growing on bare, rocky hills and sandy banks. Many improved garden forms and hybrids have been raised from this species and *P. Stellaria*, some of very compact habit, others at free growth and taller in stature than *P. subulata*. The flowers vary in colour with many shades of crimson, purple, rose, lilac and

white. *P. subulata* (Nelsonii) is a well known plant, with its sheets of snow-like white flowers in spring quite covering the foliage. Nurserymen offer a number of beautiful varieties, one of the best of which is "Vivid," with vivid rose-coloured flowers, not inaptly described as "hot salmon colour." W. L.

AN EARLY AUTUMN SHOW AT VINCENT SQUARE

THE Royal Horticultural Society's Hall was fairly well filled on September 4, but the exhibits, though good, were less interesting than on some recent occasions. The alteration in the place for "New and Rare Plants" is a decided improvement in the arrangement, and under the new method early visitors are now spared on entering the bare expanse which formerly drew the eye. It was quite the correct meeting for making the change, as there were no "New and Rare Plants" to place there and it saved a vacant site in a prominent position.

The Floral Committee found only about half a dozen or so novelties for consideration, and these were chiefly Gladioli and Chrysanthemums of moderate merits. Those, and they are many, who find an appeal in blue flowers liked the *Anagallis*, which we mention at the end of these notes, even though it did not find favour with the Committee.

■ Dahlias, naturally, filled goodly spaces, and the fine collections of Messrs. Carter Page and Co. and Messrs. J. Cheal and Sons we have reserved

for fuller notice in our account of the National Dahlia Society's Show.

In view of the Foremarke Cup competition, Gladioli formed quite an important part of the floral exhibits, even though the collections in competition fell short of anticipations. Only Messrs. Lowe and Gibson and Major Churcher competed, and the cup was awarded the former for twenty interesting varieties. Their best sorts were Al Shira, Gipsy Queen, Splendora, Titanic and Orange Gloey; while chief among Major Churcher's set were Buckeye, Red Knight and Marie Lyon. In another place he staged attractively arranged bowls of Alice Tiplady and Dorothy Wheeler.

The largest general collection of Gladioli was set up by Messrs. Kelway and Son, and this included many good large-flowered varieties, such as Sword of Fire, James Kelway Toms, Alderman, Dorothy Kelway and Prince of Orange. The daintier primulinus hybrids predominated in a noteworthy collection arranged by Messrs. R. H. Bath, Limited, and here Alice Tiplady was again much admired. A goodly vase of

Prince of Wales harmonised well with Chris. Topsy, Atalanta and J. O. Koen, three primulinus hybrids, were worthy of special attention in the exhibit staged by Mr. A. Edwards.

Roses seemed to possess unusually bright colours, and in this respect a selection set up by Messrs. Wheatcroft Brothers, who were shewing for the first time at the Hall, was very striking. They were a little unfortunate in their position, as the display would have been more successful had there been a background. Very good collections were contributed by Messrs. Alex. Dickson and Sons, Messrs. Paul, the Rev. J. H. Peuberton, and Messrs. D. Prior and Son. The principal varieties were Alice Amos, Betty Upchurch, Lady Inchquin, Christine, K. of K., Mrs. Hy. Bowles, Una, Emma Wright, Sonv. de Georges Peruet, and especially the Queen Alexandra Rose and Walter C. Clarke.

Herbaceous Phloxes were the most numerous of the general border flowers, and while they were not quite of such high quality as on some former occasions, there were many beautiful sorts on view, particularly those with soft, pleasing colours,

BEAUTIFUL AUTUMN BLOSSOMS OF WEIGELA BOUQUET ROSE WERE A FEATURE OF MESSRS. CHEAL'S EXHIBIT.

A QUAIN AND LARGE-FLOWERING BRILLIANT BLUE PIMPERNEL, ANAGALLIS MONELLII WILLMOREANA.

In the large group of Mr. H. J. Jones we particularly noted Mrs. M. van Hoboken, which is of delightful rosy mauve shade and apparently very free flowering. Thor, which is a trifle deeper in shade and has a definite carmine eye, was very attractive, as also was Riverton Jewel. A somewhat uncommon variety was the royal purple William Ramsey.

Sutton's Monthrettas were again immensely admired, and the large collection of such handsome spikes as those of the orange-scarlet Queen of Spain, the orange and crimson Queen Mary, the pale orange Una and the red-stained Henry VIII were very decorative. Mr. S. Morris set up a smaller collection, chiefly of new sorts. Copper King is well named, and is most uncommon. Rosemary, of red and yellow tones; Jessica in crimson and gold; and Joan of Arc, the best pure yellow, are the names of some of the very best.

The second crop of Delphinium spikes is now well in season, though, on account of the unfavourable season, they are not so tall and stately as in some years. But the spikes seem to be more compact and so give good colour values. Lavanda, Queen of the Belgians and Lord Curzon were very notable.

Among the various Kniphofias a vase of the graceful little K. Nelsoni minor was very pretty. Pentstemon barbatus Torreyi, Physostegia virginiana and Lilium tigrinum splendens in Mr. Amos Perry's group were very desirable. Messrs. J. Cheal and Sons had a little set of unusually good Honeysuckles in their collection of hardy shrubs. Lonicera belgica Late Red well shewed its density and free-flowering habit, while L. Scarlet Trumpet and L. Heckrottii are two other most valuable Honeysuckles.

The double pink Blackberry is rather an uncommon shrub, and we were interested to see good sprays of it (*Rubus fruticosus plena*) in an exhibit by Messrs. B. Ladhams, Limited, who also had heavily fruited branches of Shirley Prolific Blackberry.

The pot plants of their Giant Mimulus shewn by the Chalk Hill Nursery Company attracted a deal of attention, as also did their fascinating little Sempervivum plants. In between, they set up plants of a good strain of Antirrhinum. Nertera depressa in tiny pots and bearing its uncommonly clear orange-coloured fruits seemed to be a new plant to many visitors, but it has long been grown in our greenhouses and is even found to be hardy on occasion. Campanula bononiensis alba is at first sight very uncampanula-like. It produces straight, erect stems of smallish white flowers. In marked contrast were the plants of Campanula carpatica turbinata varieties as shewn by Mr. G. Reuthe. Their large, widely expanded blue flowers seem almost impossible from the close-growing little plants. A rather neglected plant of great value was also to be seen in Mr. Prichard's collection. This is Aconitum Fischeri, a perennial which stands drought well, continues to bear lovely blue flowers over a long period, and is also a good "poor soil" plant.

Some especially good Violas were displayed by Mr. Yandall. Edina, dark blue; W. H. Woodgate, pale blue; J. V. Macdonald, white; and Moseley Perfection, yellow, are the names of only a few of the large collection. Mr. Clarence Elliott had one bowl of Viola tricolor of lovely rich colouring, and he also shewed a number of fascinating little upright Irish Junipers.

Greenhouse plants were represented by splendid flowers of Streptocarpus from Messrs. R. and G. Cuthbert and their usual beautiful Carnations from Messrs. Allwood Brothers, Messrs. Stuart Low and Co. and Mr. C. Engelmann. Messrs.

Allwood specially featured their new Perpetual Borders and Allwoodii.

Messrs. Daniels well illustrated the long-keeping quality of their September Black Currant and also shewed several dishes of Apples.

NEW AND RARE PLANTS.

Anagallis Monellii Willmoreana.—This is a very beautiful and uncommon "Blue Pimpernel."

NATIONAL DAHLIA SOCIETY'S SHOW

FOR the second time this year we have rejoiced to see a special flower society overcome serious weather difficulties and give its

members and the public generally an enjoyable show. As is fairly well known, the National Rose Society seriously considered the abandonment of its summer fixture, but the optimists prevailed. Although in the case of the National Dahlia Society there was no question of any abandonment or postponement of its annual show, the management were caused great anxiety on account of the devastating effects of the furious gale which swept over the country a week beforehand. The general quality of the blooms was surprisingly high.

The imposing groups of magnificent Dahlias so well set up by such exponents of Dahlia growing as Messrs. Carter Page and Co., who received a large gold medal; the fresh and attractive collection of Decorative sorts so finely displayed by Mr. J. T. West, another gold medal winner; the charming arrangement by Messrs. Jarman and Co.; and exhibits of great value by Messrs. J. Cheal and Sons, Mr. Charles Turner and the Central Garden Supplies, received a deal of well deserved admiration.

Among all these collections were to be found the very best of all the many types of Dahlia.

In the open competitive classes Messrs. J. Cheal and Sons won many first prizes. Their vases of Homer, Queen of the Pinks and Mrs. H. B. Brandt, among the Miniature Cactus, were very beautiful. Daisy, Irene, Silver Queen and Regulus of the Pompons, shewn on frames, and especially Girlie, Electro and Daisy of the same type, in vases, were charming examples of these dainty blooms. Among their shapely singles, Marie, Leon and Kitty were perfect in form. The large Paony-flowered varieties Ethel May and Yellow Prince continued to be shapely throughout the day; while in the small Paony section, Leonie Cobb, Hector and Rosie were highly decorative examples from the same growers. All their blooms were beautifully fresh, clean and bright.

It is a semi-trailing little variety from Tunis which has angular stems, neat green leaves and bears charming blue flowers fully twice the size of the Scarlet Pimpernel. Shewn by Mr. G. G. Whitelegg.

Lælio-Cattleya × *Mrs. Medo*, Low's variety.—A handsome spike of medium size. The perianth is rich yellow. The lip, which is narrow at the base, is prettily waved and of velvety crimson colour. Award of merit. Shewn by Messrs. Stuart Low and Co.

In the class for large Decoratives Mr. H. Woolman was first with large, but perhaps rather

A FINE NEW SINGLE DAHLIA, LITTLE JENNIE (SHADES OF FAWN AND CARMINE).

rough blossoms, including such sorts as Futurity, President Wilson and Fireflare. Messrs. J. Cheal and Sons continued their successes with such excellent Collarettes as Vera, Scarlet Queen, Henri Farman and Mrs. J. Courtauld in both classes.

As usual, chief honours in the open Cactus classes went to Messrs. J. Stredwick and Son, who won the gold medal with an impressive display of eighteen varieties (six blooms of each), and first prizes in other classes. Their very best blooms were Mrs. A. T. Barnes, Silverhill Pink, Mrs. A. Harvey, Gigantic, Supreme, Gloriosa, Lucien, Highwayman and John F. Woolman. The best twelve Cactus flowers on boards were shewn by Mr. H. Woolman, who included perfect blooms of Abbotsford, Meridian, Mammoth and Mrs. C. A. Gilliatt. Messrs. W. Treseder,

Limited, alone in the classes for Show and Fancy Entries, but were awarded the first prizes for excellent examples of this old type. Duchess of Albany, Merlin, Chas. Wood and Warrior are the names of only a few of their good blooms.

The amateurs' blooms came from over a wide area, embracing Bedfordshire, Hampshire, Cornwall and the Channel Islands. The chief prize winners were Mr. W. G. Cramp, Streatham; Mr. A. T. Barnes, Bedford; Mr. A. Brown, Leagrave; Mr. M. Howard, Chesham; Mr. A. F. Popfield and Mr. S. T. White, both of Southampton. The quality of the blooms was gratifyingly high and this section was a good feature of the Show. The newly arranged classes for amateurs who grow their own blooms unaided were very popular.

NEW DAHLIAS.

The Joint Dahlia Committee found forty-three seedling Dahlias awaiting judgment, and although the senders of a few must have been of decidedly optimistic temperament, the majority of the novelties reached a high standard of excellence. Each of the varieties described below, which are selected for trial at Wisley, promises to be a really good garden plant. Besides these, Miss Ivens, a pretty Collarette, shewn by Messrs. W. Treseder, Limited, and Lydia, a charming little Pompon with exceptionally long stems, were of considerable merit. The latter was shewn by Messrs. J. Cheal and Sons.

Little Jennie.—A most charming single of perfect rounded shape. It is of shining fawn colour, tipped with rosy mauve, and has a neat carmine zone. Shewn by Messrs. W. Treseder, Limited.

Mrs. Perry.—A very uncommon Collarette of medium size and bright scarlet colour. The quills, which are one half the length of the petals, are the same colour. Shewn by Messrs. W. Treseder, Limited.

Nutfield Priory.—A very graceful miniature Peony. The ground colour is a good yellow and this is flushed with pale orange. Shewn by Messrs. J. Cheal and Sons.

Defiance.—A splendid miniature Peony. The yellow colour is heavily flushed with warm scarlet. As the name has already been used, this variety must be renamed. Shewn by Messrs. J. Cheal and Sons.

Victory.—This is another variety to be renamed. It is a giant Decorative variety of cactus-like habit and rosy mauve colour, with a yellow centre. Shewn by Messrs. J. Stredwick and Son.

Zebra.—An ugly bloom. Its merits seem to be that the striped flowers have longer stems than those of any other bicolor Cactus Dahlia—which is pursuing an ideal to excess. If the variety lives it must have a new name, as there is already a Zebra. Shewn by Messrs. J. Stredwick and Son.

Thos. Want.—A magnificent show Cactus having the ideal long rolled incurved florets. The colour is deep coral. Shewn by Messrs. J. Stredwick and Son.

Thos. Ewbank.—A most delightful miniature Cactus of dwarf habit, very free-flowering and producing well made petals of geranium-scarlet colour tipped with rose. Shewn by Mr. A. J. Cobb.

Vive la France.—Another excellent miniature Peony from the University Gardens, Reading. It is of intense velvety crimson colour and is a desirable variety in every respect. Shewn by Mr. A. J. Cobb.

Amun Ra. This was the giant flower of the Show. The blooms measured over 6 ins. across and are of primrose yellow colour, prettily flushed with apricot; the centres are reddish. It is a flattish Decorative bearing broad, pointed florets. Shewn by Mr. H. Woolman.

GLADIOLUS PRIMULINUS HYBRIDS

WHAT a coming of age it will be when in 1925, *Gladiolus primulinus* will be celebrating the twenty-first anniversary of the first public appearance of its flowers at a show in England! It is impossible for anyone who has not kept up with its numerous descendants to imagine what it will be like. Why so? Because even more than the advent of the Darwin has done for Tulips, or the unexpected appearance of the Spencer type has done for the Sweet Pea, the chance find of *G. primulinus* at the Victoria Falls on the Zambesi has accomplished for the *Gladiolus*. Or all the *Gladioli* that Africa has given to us, none surely has had a wider and more far-reaching influence upon the family than this—its last gift and (may I not say?) its best.

I am moved to write about *primulinus* hybrids by the unexpected arrival of two large market flower boxes from Messrs. R. H. Bath of Wisbech, crammed full of spikes of these very delightful plants. They have filled every available suitable receptacle in the house and turned the rectory hall into a *Gladiolus* garden. I have never had a *primulinus* or a *primulinus* hybrid growing in the "flesh." My *Gladiolus* growing—and I once had a very decent collection—was cut short by a sudden severe frost, which proved too much for the protective measures wherein I had trusted, and left me a sadder but a wiser man. I have never made a new start. Hence it has been a reminder of old times to have lived with a collection once again for a few days. The first thing

I must say is that the introduction of this new blood has improved the race out of all recognition in the subtle warmth of colour and the slender gracefulness of spike which carry the smaller, saucy-looking blooms of the new type. Pretty well every section—it is not an anachronism to use this word—must have been mated with *primulinus*. But blue-purple like we see in the famous Baron Hulot seems to have been left out. Perhaps the colours would not "take," or the colour result of the cross has been found to be anything but pleasing. As a compensation we have enough pink, red, orange, yellow and white shades to satisfy most people. A list of some of their names, taken from Ridgway's Colour Chart after a careful matching of their flowers, bears this out—viz., scarlet, scarlet red, peach red, spectrum red, Orient pink, shell pink, geranium pink, cosine pink, begonia rose, thulite pink, pinard yellow, light green yellow, sulphur yellow, capucine orange and so on. In form and habit these *primulinus* hybrids are to the old thick-set, heavier spikes of the *gandavensis* and *Childsii* sections what the daintier, loosely clothed spike of *Oranje Boven* is to the heavier and more tightly packed spikes of the orthodox Dutch *Hyacinths*. How well I remember the Horticultural Club dinner in the evening of the first day of the first Forced Bulb Show at Vincent Square! I had to open the discussion on the flowers in the hall, and in the course of my remarks produced a spike or two of *Oranje Boven* and said what a beautiful and pleasing variety it was, at the same time

expressing the hope that we might have more of them. It was altogether too much for the veteran, Mr. G. H. van Waveren, who followed. He took up the flowers and flung them down on the table to shew his scorn of what to him were pitiable objects. His verdict was wrong. Beauty has conquered orthodoxy. Most big firms now put *Oranje Boven* in their bulb lists, presumably because it sells. To outline future happenings is like skating over thin ice; but the *primulinus* hybrids have already made such a good start with the flower-loving public that I may use, with regard to their future, the very words of a brother clergyman—Dean Herbert of Manchester—who is certainly one of the greatest authorities of all time on any matter pertaining to bulbs and who, in writing of the future of the *Gladiolus* long before *primulinus* or even *Saundersii* were ever thought of, said: "I am persuaded that the African *Gladioli* will become great favourites when their beauty in the open border, the facility of their culture, and the endless variety that may be produced from seed by blending the several

THE APTLY NAMED GLADIOLUS (PRIMULINUS) SALMON BEAUTY.

species are fully known; nor will they be found to yield in beauty to the Tulip and Ranunculus." My own comment is, if this last remark were true *then*, how much more true is it *now* that primulinus has given us something of its own fairy-like grace and *petitness* to the more solid-looking beauties of the past. This new type equals the older ones for garden decoration, more than equals them for growing in pots, and much more than equals them for using for cutting.

The prophetic confidence of Messrs. R. H. Bath is given a concrete form by a plantation of two acres of these hybrids. There are other firms, too, like that of Lowe and Gibson, who also are expressing their belief in the future in a visible manner at Crawley Down. No end of primulinus hybrids will be wanted. Only let them get better known; and, *above all*, let each one show its provenance, so that he who runs may read.

JOSEPH JACOB.

THE MONTBRETIAS

IN some gardens these lovely hardy border plants are cared for and grown well, but in the majority of gardens, if they are not neglected altogether, very little trouble is taken with them. When properly cultivated the plants form very striking clumps in the border. Although there are some extraordinarily fine new varieties, I think very few growers are prepared to discard the old *M. crocosmaeflora*. There is room for it and the larger-flowered ones. *Crocosmaeflora* makes a brave show in the border, especially when the bulbs are planted singly and sufficiently far apart to admit of growth without undue crowding of leaf and stem or robbing of roots. One frequently sees plants growing like sheaves of corn in appearance and having fifty bulbs where there is only room for five. Moreover, this old plant is quite happy outdoors in an English winter, which the new ones are not. Few of the combs fail to start and grow away even in a naturally cold clayey medium, but the ideal soil for this plant, and the Montbretias generally, is one of average strength and thoroughly well drained. Retentive soils should be made more porous by adding well rotted leaf-mould. In newly planted shrubberies, to avoid bare patches of soil for several years, Montbretias may be successfully planted in clumps of from ten to two dozen. By the time that this stop-gap planting is unnecessary, the bulbs will be ready for lifting, grading and replanting in another border. As a dry border plant this is difficult to surpass. I have several clumps which have withstood much dry weather, but it would not be justice to them to leave the bulbs longer in such a position, so in due course a more suitable one will be found. Well matured bulbs of good size potted in a nice sandy compost in the autumn will afford a supply of flowers for the greenhouse or conservatory, and are of special value in town and suburban gardens. When potted the bulbs must be kept quite cool till roots form freely. Plunge the pots under old ashes or coco-nut fibre.

The following are some of the best of the newer varieties: Lord Nelson, dark orange; Star of the East, orange; Lady Hamilton, light orange; Drap d'Or, chrome yellow, large flowers; Etoile de Feu, vermilion with yellow throat, large; Germania, bright red, large; Phare, scarlet and orange; and Sulphurea, deep chrome yellow, very large. Splendid for pot culture are the following: Drap d'Or; Soleil Couchant, golden yellow, dwarf; Californica, pure yellow; Phare and Gerbe d'Or, dark orange. In the open borders the average height attained is 2ft. G. GARNER.

CORRESPONDENCE

PRIMULA LA LORRAINE.

AMONG the many interesting Primulas exhibited by Dr. John Macwatt of Duns, at this year's Chelsea Show, I noticed a nice little group of this hybrid Primula, raised, I believe, by Messrs.

and white, striped with purple. In the open I have never had it satisfactory unless when covered rather a "bull" that, perhaps, but readers will understand that I mean temporary protection on the open ground. In many winters, unless

A SMALL PORTION OF DR. MACWATT'S PRIMULA EXHIBIT AT LAST CHELSEA SHOW. "*La Lorraine*" is the considerable group of *Sieboldii*-like Primulas right in the centre of picture.

Lemoine et Fils of Nancy, France, some years ago. I understand that it is a hybrid between *P. Veitchii* and a variety of *P. Sieboldii*. It has not, I think, been shown in such a nice group before, and I was glad to know from Dr. Macwatt that it does well with him and is a flower he thinks highly of. It does not appear to have the same defect that is possessed by the *Sieboldii* varieties of vanishing from the garden without any apparent cause and is more akin to *P. Veitchii* in this respect. It has large, well formed flowers of a warm deep pink and the group shown by Dr. Macwatt made quite a nice feature in a more than usually interesting collection which was highly appreciated by all Primula lovers.—S. ARNOTT.

THE WINTER CROCUS.

THE number of cultivators of the Crocus species appears to be increasing, though not very rapidly. It may be well, therefore, briefly to refer to *Crocus hiemalis*, often offered under the heading of the "autumn-flowering" species. It is generally due to bloom about December and January—a time when sun is scarce and other weather conditions far from suitable for such a sun-worshipper as the Crocus. In consequence *C. hiemalis* is of little use in the open, unless it is covered with a hand-light or bell-glass. It is a pretty little flower, small in size even for a Crocus,

in a very sunny place and covered with glass, it never opens, although it may remain in bud for a long time as if awaiting the sun, until it becomes a mass of pulp through the effects of the winter's rainfall. The moral is to leave *C. hiemalis* alone, unless you are prepared to cover it, or, better still, plant it in a pot and flower it in the alpine house or cool greenhouse.—NORTHERNER.

THE CARPENTERIA.

IN reference to the letter of "A.R." in your issue of the 25th ult. concerning the paucity of *Carpenterias* grown in this country, I would like to say that two varieties of that splendid shrub have flourished against a south wall here for twenty years or more, flowering luxuriantly every July. I enclose specimens of the two plants, from which it is plain that they may be classified as major and minor, major having much bigger leaves of a lighter green than minor. The blooms follow the foliage in size.—REGINALD RANKIN, Bt., Hereford.

[The foliage and flower-sprays sent differentiated the two varieties very clearly.—ED.]

THE ÆTHIONEMAS.

GENERALLY speaking, *Æthionemas* are excellent plants for dry, sunny positions or rocky ledges in the rock garden. They are not at all

difficult to grow, but once established they much dislike disturbance. They are best raised from seeds grown on in small pots and planted out into suitable positions when large enough. The soil should be well drained and contain plenty of grit with some broken limestone added to it. Among the best kinds are *Æ. armenum* from Armenia, with long racemes of pale pink flowers on branching stems about 6 ins. high; *Æ. coridifolium*, "Lebanon Candytuft," forming small tufted plants 6 ins. high with rosy pink flowers; *Æ. grandiflorum*, from Persia, very handsome, forming small bushes of wiry stems 1 ft. high or more, clothed with glaucous leaves, and producing during June and July long, slender racemes of large, rosy pink flowers; and *Æ. ibericum*, low-growing, being only a few inches high, with white or lilac-tinted flowers in early summer. *Æthionema pulchellum*, forms small bushy plants with twiggy branches, covered with glaucous leaves and producing in spring racemes of pale rosy purple flowers. It is a native of Armenia, and is a hardy perennial if planted in a sufficiently well drained and sunny position. A choice little plant is Warley Pink, apparently a hybrid of *Æ. armenum* and one of the other species. It is of very dwarf bushy habit, covered in spring with charming rosy pink flowers.—S.

A FINE "ARALIA."

THAT popular Japanese evergreen shrub generally known as *Aralia Sieboldii* is frequently erroneously called the Castor Oil Plant; it is

FATSIA JAPONICA OUTDOORS IN SCOTLAND.

now officially named *Fatsia japonica*. It is a favourite room plant and is highly suitable for indoor decoration. Nicholson describes it as "half-hardy, height 3 ft. to 5 ft." I have come across several specimens of from 3 ft. to 4 ft. in height which have proved hardy in sheltered spots in Edinburgh and surrounding district, but it was only the other day that I was introduced to a specimen 9 ft. high, with a spread of the same dimension, in the back garden of Mr. A. Cherry, Eskside, Musselburgh. It has flowered several times and it has doubled in size since Mr. Cherry

first occupied the house seven years ago. A former occupier knocked it out of its pot about the year 1909 and without thought stuck it into the ground in the back garden. I am sending you a photograph of the plant, which I hope may be suitable for reproduction, as I do not think the plant has an equal—in the East of Scotland, at any rate.—CHARLES COMFORT.

PLANT CLEMATISES NOW

THE great masses of Clematis flowers which now open day by day make us fully realise what a valuable addition these climbers are to the garden, both in town and country. There is no need to devote a bed or border to them; we can get hundreds of flowers from a plant in a small portion of space and, if well tended, these will be large, decorative and distinct.

It is usual, and certainly best, to purchase plants established in pots, but, should these be pot-bound, the roots should be carefully disentangled and spread out when planting. It is advisable to get the plants well established a considerable time before cold weather arrives, and the latter end of September will be found none too soon, especially in districts where the soil is cold and of a heavy nature. As pot plants they are most interesting to cultivate and when in flower a well grown specimen is really magnificent. I do not advise liquid manure to be given to pot-grown plants. I have always found that this arrests the growth. It is far better, therefore, to apply a top-dressing of material from an old hotbed to the top of the pot, which always gives excellent results. A little bonfire ash should be mixed with the compost and is most helpful to the plants.

When planted in the open ground the plants delight in a good silky loam, with which should be incorporated a certain proportion of burnt vegetable matter, a little chalk and some well decayed manure from an old hotbed. Clematises enjoy good living, and when in the open ground delight in an occasional dose of liquid manure.

When planting at the foot of a wall, whether house or other, it is advisable to dig the soil deeply, considerably more deeply, in fact, than the roots of the plant are set, and if the soil is poor—as is generally the case in such positions—remove a couple of barrow-loads of it and replace with better and richer compost. The extra labour is well worth while, for when once planted we hope to have the plants in being for years, and there will never again all through their lives be an opportunity of introducing fresh soil well underneath them; henceforth, a top-dressing is all they are likely to receive. When filling in the new soil before planting, tread it well down. Failure with newly established plants is frequently due to neglect of this small attention. Clematises are admittedly capricious, and it is well to find out what they like and endeavour to please them, and then they will repay with a marvellous display of flower.

The Clematis may be put to a great number of uses. The one we are most familiar with is as a climber for the house wall. We often see it, too, as a covering for arches, but there is an even more pleasing way than this of growing them, and that is in allowing them to cover old tree stumps. They can also be used with fine effect to "face" a raised bed if properly trained to supports.

In a large garden the Clematis can even be used as a permanent bedding plant, when some wonderful effects can be obtained. Wires should be stretched over the bed at a height of 2 ft. from the soil, and on these the plants should be trained. One bed like this I saw last year had the little white early-flowering *C. montana grandiflora*, *C. Jackmanni superba* and the double-flowered Countess of Lovelace. From a little distance the effect was splendid, and I do not think I have seen another planting to surpass it. With a proper selection of varieties we can have the Clematis with us early and late, and yielding flowers from May till the end of October.

Even the wild *C. Vitalba* is very pretty in flower, and its beauty does not fade when the blooms die, for the silvery tangle of the seed vessels is also very lovely. If there is an out-of-the-way corner in the garden, this Traveller's Joy should be given a place. When used in combination with the Ivy, charming effects may be obtained for the winter garden. The pergola also claims its meed of Clematises quite as much as Roses. What plants associate better together than the deep purple Clematis Jackmanni and that glorious old Rose Gloire de Dijon. They should be allowed to grow together; they will do one another no injury and they naturally flower together.

A very beautiful but uncommon species is *Clematis alpina*. It can be made good use of in the rock garden, climbing over some old tree stump or over the rockwork. The flowers are of a delicate lilac tint. It requires a deep root-run and, if possible, a silky loam with mortar rubble added. As all acknowledge, the Clematis is very beautiful on walls and buildings, but it is not really so effective as when grown to cover trees or shrubs. To see *C. Jackmanni superba* in the branches of a tree with its masses of intense blue purple is a wonderful sight and frequently gives that touch of character to a garden that is so often lacking.

To name just a few good modern garden varieties, among violets having a good deal of red we have Marcel Moser and King Edward VII, while Queen Alexandra is lavender, shaded mauve-purple at the base of the petals. Then among the delicate pale lavender blues mention should be made of W. E. Gladstone, Venus Victrix and Belle Nantaise. Two beautiful whites are Mrs. George Jackman and alba magna. Still, all these beautiful colours notwithstanding, we associate the deep blue-purple of Jackmanni superba with the Clematis, and for any extensive planting I should certainly use this characteristic colouring as the "back-bone." F. H.

FORTHCOMING EVENTS.

September 18.—Royal Horticultural Society's Fortnightly Meeting.—Winchester Horticultural Society's Meeting.

September 20.—National Rose Society's Autumn Show, to be held at the Royal Horticultural Society's Hall (two days).

October 2.—Royal Horticultural Society's Great Autumn Show at Holland Park Hall (three days).

INSECTIVOROUS PLANTS—II

Drosera and Dionaea.

AS we have a British representative of the Sundews that is not uncommon in boggy places, it seems fitting that we should deal with this among the first of our carnivorous plants. The British species is, it is true, only annual in duration and is also quite a small representative of its race, but there are several other and larger and handsomer perennial species which are sometimes met with in our greenhouses. *D. rotundifolia*, our native form, is rosette-like in its arrangement of the foliage, the leaves being round and the whole disc thickly beset with red inflexed hairs, each of which carries its drop of delusive sticky secretion that looks so amazingly tempting if you are a nectar-loving fly. From the centre of this rosette of leaves rises a slender stem which bears its white flowers in July and August, followed by the wee seeds which are to produce the following year's crop of *Drosera*.

If one would grow this under cultivation, it must, of course, be done either in the open air or a cold frame, not on any account in a greenhouse where the temperature would rise too high for its health and happiness. With this exception and the fact that you must keep up your stock by means of annual seed sowing, it responds to identical soil and other conditions to the foreign varieties. Indeed, culture is quite a simple matter, and their happiness is ensured by well drained shallow pans which are filled with a compost of living sphagnum, charcoal and a little peat. These pans should be mounded up slightly towards the centre, somewhat like a pie, and when sown or planted should be stood in saucers that are kept filled with water so as to ensure those boggy conditions which are so congenial. The fullest possible exposure to light at all times is another essential. If you are sowing seeds of our native variety, do not fail to do this as soon as possible after they are ripe—for that is Nature's way.

Drosera linearis is the species from abroad which is usually met with under cultivation, and with this you have three alternative methods of increasing and maintaining stock. Firstly seed, then division and lastly root cuttings. The latter is especially successful, and all that is necessary is to cut the roots into pieces about half an inch long and lay these on a shallow seed pan partly filled with peaty soil, afterwards covering the cuttings by a further half inch of similar compost. Place the pans under a bell-glass in a warm greenhouse and keep them close and moist. In a very short time small swellings begin to appear on the surface of the cuttings, and these gradually increase in length until they push their way through to the surface and begin to put out leaves like those of the adult plants. When they have grown sufficiently, they may be lifted and potted up singly, and soon make excellent plants. There is quite a number of species of these Sundews from various parts of the world, a specially remarkable one being the Australian Sundew. This reverses most of the features with which we are familiar in that it makes its home in very dry places and, to meet the difficulty of lack of rainfall, forms a thick bulbous root which acts as a reservoir to store enough moisture to carry the plant through the times of drought. The South African *Drosera capensis* is an extremely beautiful plant, forming dense rosettes of long, narrow leaves of which the margins are densely covered with glandular hairs, each one of which carries its bead of deception, so like (in appear-

ance) a drop of glistening honey. It is but a slender chance, indeed, for any insect so unlucky as to be snared upon those fearsome globules, for a touch of the finger will show that those sparkling drops are not only extremely sticky, but that the juice of which they are composed is extremely elastic, and thus the more the creature struggles the more hopelessly it becomes enmeshed.

Dionaea muscipula—more familiarly known as Venus's Fly Trap—is in many ways the most elaborate insect-eating plant that exists. It adopts the rosette formation, with more or less prostrate leaves round the base of the flower-stalk. It is these leaves that constitute the wonder of the plant, for they consist of a spoon-shaped stalk which is constructed at the mid-rib

A PAN OF THE AUSTRALIAN SUNDEW, *DROSERA SPATHULATA*.

and armed with the most marvellously elaborate catching mechanism it is possible to imagine. These leaves broaden towards the end into a blade, the two halves of which close upon each other exactly in the same way as a book with a spring back-hinge. Along either margin of the leaf are rows of teeth that fit into one another when the leaf closes, just like a rat trap. The surface of the leaf at the centre possesses numerous digestive glands, capable—when a meal is offered—of pouring forth the acid digestive juice.

Even yet, however, we have not reached the heart of the *Dionaea's* secret. On looking very closely one sees that on each half of the leaf blade there are three thin hairs. These, like the antennae of a butterfly, are the sensitive point, and the merest touch upon these—if the touch is that of a nitrogenous insect—immediately sets the whole mechanism in operation. Note how the hairs rise obliquely when nothing is upon them; now imagine that a small fly has alighted and just touched one of the hairs. Immediately everything is fevered activity. The hairs fold flat, the leaf begins to close, those terrible teeth interlock, and within eight or ten seconds are tightly closed and a protuse secretion from the digestive glands takes place. There is one little fly less in the world and the *Dionaea* has gathered its nitrogen. The digestive process occupies some time and then the leaf expands again. The plant cannot be accused of greediness, however, for, after "eating," the leaf remains torpid for some time and refuses

to respond to the stimulus of further nitrogen when offered.

As a greenhouse plant this "miracle of nature," as Linnaeus has so aptly termed it, is very easily cultivated. Use the same flat pans as have been recommended for the Sundew and fill them with a mixture of charcoal, peat, leaf-soil and living sphagnum moss. A very important point is free drainage, for stagnant moisture is quickly fatal. During the period that the plant is in active growth free supplies of moisture must be provided, but keep drier during the autumn and winter. As the pans cannot be stood in saucers of water as advised for the Sundews owing to this detestation of stagnant moisture, it is best to place a bell-glass over the plants, as this checks too rapid evaporation. The plants bear white flowers in June and, to ensure a supply of seed for raising further plants, these should be cross-fertilised so as to ensure their setting their seeds freely. The small black seeds ripen in about a month, and should then be sown at once on the surface

of a pan filled with similar compost to that advised for the plants. Keep moist and cover with a bell-glass.
H. W. CANNING-WRIGHT.

DIPELTA FLORIBUNDA

AMONG the recent very numerous discoveries in China are four species of the interesting group called *Dipelta*. Allied to the Honey-suckles, and perhaps still more closely to the *Diervillas*, they are remarkably distinct from both in their fruits, which have attached to them two shield-like discs of the same texture as the wings of Elm seeds. This beautiful species was introduced by Wilson from Central China in 1902, and has flowered annually in May and June during the last few years. The blossoms are funnel-shaped, 1 inch to 1½ inches long, dividing at the mouth into five rounded divisions and measuring there 1 inch across; they are pale pink, stained with yellow in the throat, and have a charming fragrance. We have not yet seen this shrub at its best. Wilson thought so highly of it that, not being able at first to obtain seed, he sent home living plants to Coombe Wood. It is deciduous and described as being 10ft. to 15ft. high in a wild state, the bark of the stem and older branches peeling off in thin flakes. The two discs which shield the fruit are three-quarters of an inch across. It is a shrub that likes generous treatment at the root, and may be propagated by cuttings.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Onions.—The spring-sown crop must be lifted immediately it is ready, otherwise the bulbs may start into growth again. Storing Onions satisfactorily seems a difficult problem to many people. A cool, dry shed should, if possible, be chosen, and they should be arranged thinly over the floor, tied up in small bunches and suspended, or made secure to sticks. The bulbs must be well ripened before placing them in store, and any that have long necks should be used up in the near future. Cold weather will not harm Onions and plenty of ventilation is necessary.

Herbs.—Young plants of many herbs give the best results. The different forms of Thyme and Sage may be increased from cuttings at this season. A sandy soil is needed, and the side shoots, about 4ins. in length, will readily form roots either in a cold frame or the open border. They should be transferred to their permanent quarters next spring.

Potatoes.—Many of these have completed their growth, and where such is the case they should be lifted and placed in the store shed. There is no need to wait till the haulm has died down, for when the tubers are fully developed they are better out of the soil and placed where they are less likely to be attacked with disease.

Cabbage.—The old bed that has been producing a crop of "sprouts" since the spring may be destroyed and the ground trenched and well manured when an opportunity occurs. If labour is available, it always pays to trench the ground deeply, but some gardens in this district have the solid rock so near the surface that this is impossible. In such cases all the old potting compost and any other soil available is wisely added to the garden.

The Flower Garden.

Paths.—The various walks in the pleasure grounds and gardens should be clipped with the edging shears and kept free from moss and weeds. There are several weed killers on the market, and as a rule it pays better to employ these than to resort to a home-made article.

Sweet Peas.—It is usual to sow the seeds in the spring and, where glass is available, in pots for early flowering, but there is no reason why a sowing should not be made in the open during the next few weeks. A piece of ground that was well manured for a previous crop should be chosen and the seeds should be sown rather more thickly than is usual. It is not advisable to sow expensive varieties, because slugs are often troublesome and, if the winter is very wet, the seedlings may perish. In spite of this, however, the flowers from an autumn sowing are very acceptable; they are earlier than those from the spring sowing, and are strong and of fine substance.

Liliums.—Most of the really hardy Lilies can be planted now or directly the bulbs are available. Good border Lilies include candidum, croceum, chalcedonicum, Henryi and the various forms of the Tiger Lily. They will succeed in any good garden soil and should be planted from 3ins. to 6ins. deep. Surround each bulb with a layer of sand and, if the soil is heavy and wet during the winter months, a few pieces of peat at the base of the bulb will help to prevent the roots from decaying. Lilies require plenty of moisture when growing and, if they are planted among shrubs, it may be necessary to afford them water during a dry season.

Bulb Planting.—The planting of Daffodils, etc., should be proceeded with, as they enjoy a long season of growth.

The Hardy Fruit Garden.

Bush Fruits.—After a time such fruits as Currants and Gooseberries deteriorate and it becomes necessary to renew the bushes, but to maintain a supply, only a portion of the fruit quarters should be dealt with in one season. Old trees should be uprooted and burnt and the ground be cleared of weeds, manured and trenched. Both Gooseberries and Currants may be planted 4ft. apart. White Currants should be included, although for most gardens a few bushes will suffice. The best varieties are White Dutch and White Transparent. Among red kinds, Fay's Proline is a valuable variety, and other good sorts include La Versailles (a heavy cropper) and Ruby Castle. Of Black Currants, the best are Baldwin's Black, Boskoop Giant and Ogden's Black. The number of varieties of Gooseberries

found in fruit catalogues must bewilder the beginner, but he confines himself to one kind. Whinham's Industry should be chosen. Other useful sorts are Langley Beauty, Broom Girl, Duff's Mistake and Warrington.

Strawberries.—Where the plants are still producing runners it will be necessary to remove them as they appear, or the parent plants will be weakened. Keep the bed free from weeds.

Fruits Under Glass.

Vines.—In many vineries there will be a number of ripe bunches and, in order to keep them in good condition, it will be necessary to examine the berries occasionally and remove any that may be damaged or showing signs of decay. This is most important, for if these are allowed to remain, the whole bunch will be rendered unfit for use. Wasps are often troublesome and destructive, so it may be necessary to fix wasp-proof netting or muslin over the ventilators. Lateral growths should be pinched to prevent the obstruction of light to the rods.

Pot Fruit Trees.—Any trees that produced a late crop should be given attention in regard to potting, either placing them in larger receptacles, or pricking out a quantity of the old soil and replacing it with good quality loam. After being disturbed the trees should be syringed two or three times each day if the weather is hot. Do not let the roots suffer for lack of moisture, a remark which applies to all fruit trees, especially those in pots.

T. W. BRISCOE.

(Gardener to W. R. Lysaght, Esq.)

Castelford, Cheltenham, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Celery.—Celery, unless planted rather late, should now be ready for a second earthing up. Less check is given to the plants when several light earthings are given than when only two or three at the most are given. Break the soil fine before working it in among the plants, taking care that none of it gets into the hearts. As stated in this column previously, if clean sand is easily procurable and is used among and immediately around the plants, beautifully clean sticks of Celery will be the result.

Potatoes.—Any second earlies which are still undug should, as the haulms ripen, be lifted and pitted. Sufficient second-size tubers should be selected for seed and be arranged on a hard surface to green for a fortnight, after which they should be arranged thinly in a cool, airy structure. Should the dreaded disease *Phytophthora infestans* appear among the late varieties, spray promptly either with any of the prepared sprays on the market or prepare a spray as follows: four parts of sulphate of copper and quicklime to 100 parts of water.

Spinach.—Those who took the precaution of raising and planting a stock of New Zealand Spinach will have been reaping the benefit for some time past, and will continue to do so until sowings made at the beginning of August turn in or until the plants are damaged by an early frost, for New Zealand Spinach is far from hardy. Those who did not take the above precaution will be able to fall back for an occasional dish on Spinach Beet or, better still, on the leaves of Seakale Beet.

Fruits Under Glass.

The Orchard House.—The bulk of the orchard house trees will, ere this, have ripened their fruits and have been denuded of them, and should now be in the open air. The present is a fitting time to overhaul the entire stock and give the trees whatever attention they may require. First attention should be given to any trees requiring repotting so that they may be able to lay hold of the new soil before winter sets in. It is always safer to underpot than to overpot. Good sound loam with the addition of some bone-meal will suit any of them, but Figs, especially, will be benefited by the addition of some old mortar. Prick the ball with a wooden peg and, in the case of trees which are occupying the maximum size of pot, reduce the ball a bit by the same means. In the case of trees only requiring top-dressing, remove about 2ins. of the surface soil with the aid of the wooden peg, and then apply a top-dressing similar to that recommended for repotting but with double the amount of bone-meal. Do not apply any concentrated fertilisers at present. If the drainage has in any instance gone wrong,

knock the ball out of the pot and put matters right. Plunge the pots in coal ashes to prevent injury later on either to pots or roots by frost. Delay pruning for a little.

Peaches and Nectarines.—Trees from which the fruit has been picked and of which the foliage is decaying should have the process of defoliation accelerated by passing a new birch broom rather lightly over the trees, the movement to be from the centre to the circumference; this will give the wood a better chance of ripening. In the case of trees ripening off their fruits, see that they are provided with a catch-net to prevent damage to falling fruit, giving attention also to picking the fruits as they fully ripen.

Vines.—In houses where fruit is hanging, maintain a dry, buoyant atmosphere, and attend to cutting out any decaying berries or they will be the means of damaging others. Pot Vines which have shed their leaves should be top-dressed or repotted as circumstances require.

Melons ripening off their fruits will require rather more fire-heat, especially should sunless weather occur. Admit a moderate amount of fresh air on all favourable occasions and maintain rather dry conditions at the root.

Vegetables Under Glass.

Tomatoes.—Second crops will now be ripening off their fruits and must receive all possible assistance. Apply sufficient fire-heat to maintain a buoyant atmosphere, ventilating cautiously on all favourable occasions. Do not hesitate to remove a moderate amount of foliage where it is intercepting the light, a factor for which there is no substitute.

Cucumbers.—Maintain a brisk temperature, see that the plants are well supplied with moisture at the roots and, although a moist atmosphere is still necessary, less water will be needed to maintain it, as evaporation is now taking place more slowly. Thin out the growths rather more severely now to ensure the admission of sufficient light. Stop all shoots at one joint beyond the fruit. Cut fruits will now keep good for a considerable time in a cool place.

The Flower Garden.

Sweet Peas.—Another fortnight will finish the Sweet Pea season. It is not worth while applying further stimulants, and the most that can be done for them is promptly to cut away all spent blooms. A sowing should now be made in 3½in. pots for early outdoor supplies next year. Plain loam plus a little sand forms a suitable rooting medium, as the object is to build up firm, short-jointed plants. Place the pots in a cold frame and keep close until germination takes place, after which ventilate freely.

Phloxes.—Unless new stock is raised every few years, the quality of the flowers will deteriorate. Propagation can be carried out by division, but plants raised from cuttings are superior to those raised by division. Cuttings taken now can be rooted alongside Pentstemons.

The Bulb Order.—If not already attended to, the bulb order should be placed without delay. The size and character of the order must depend upon two considerations: first, upon the cultivator's plans; and, secondly, upon the state of the funds, for although much can still be done with a modest outlay, the fact remains that bulbs cost nearly double what they did in pre-war times. For bold masses dependence must be put upon Daffodils, Tulips and Bulbous Irises, also to a smaller extent upon Hyacinths. Lilies have always a fascination for the lover of flowers, and a number of them of much merit are still moderate in price. These include the Madonna Lily, the Nankeen Lily, the Scarlet Turk's Cap and the Leopard-spotted Lily. If not already possessed, the merits of the following should not be overlooked: Iris reticulata, Sisyrinchium grandiflorum, Dog's Tooth Violets, Chionodoxa and Scilla sibirica and sardensis.

CHARLES COMFORT.

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mans, Midlothian.)

GREENHOUSE AND CONSERVATORY.

Lilium longiflorum.—The first consignments of this Lily are now on hand. Immediately the bulbs are received they should be potted up, as Lily bulbs soon suffer from exposure to the air. They may, according to the size of the bulbs, be placed three or four in 6in. or 7in. pots, leaving plenty of room for a good top-dressing when the plants are in growth. They should be stood in cold frames until well rooted. No attempt should be made to force them until the pots are full of roots.

Pot Roses that have been placed outdoors during the summer should now be taken in hand and, if necessary, repotted. Use a good loam for this purpose, adding a 6in. potful of boned-up to every bushel of soil and enough clean coarse sand to ensure free drainage. For their size, Roses require fairly large pots, and plants in small pots may have a shift into a larger size. For example, dwarf Polyantha Roses that were flowered in 5in. pots should now be moved into those of 7in. size, in which they should make fine specimens and remain in flower for a long time. This class of Rose is very useful and dependable for pot work. If a batch of cuttings was put in outdoors last autumn, they should now have made nice plants, which next month may be lifted and placed in 5in. pots. Such plants will get well established at the root and can be used for the greenhouse next spring. Towards the end of October or beginning of November another batch of cuttings should be put in outdoors to keep up the supply. *Jessie, Orleans, Red Orleans, Mrs. Cutbush, Catherine Zeimet and Coral Cluster* are all excellent for this purpose.

Established Roses that are in large enough pots and are in good condition at the root will merely require some of the surface soil taken away and replaced with a good top-dressing. Climbing varieties should be carefully secured to suitable stakes. After overhauling they should be plunged in an ash-bed outdoors until such time as they are required for forcing.

Irises.—Many of the small bulbous or tuberous-rooted Irises are very useful for growing in pots or pans. They are specially useful for the small unheated greenhouse, as they only require the shelter of a cold frame until they come into flower, when they may be removed to the house and their beauty enjoyed in comfort. Some of the species and varieties suitable for this purpose are *H. alata, Bakeriana, Danfordiae, orchoides* (and varieties), *Vartan, Histro* and *persica*, together with the sweet-scented *Iris reticulata* and its varieties. *Iris tingitana* is also very fine, but requires larger pots than most of the others mentioned, the 6in. or 7in. size being best for this species, placing four or five bulbs in a pot. The many fine varieties of Spanish and English Iris may also be grown in pots or, if required in quantity for cut flowers, in boxes.

Iris unguicularis (better known as *I. stylosa*) and its varieties flower during the winter and spring, and although they are hardy in warm situations in the south and west, slight frosts damage the flowers. It has always been surprising to me that this beautiful sweet-scented Iris is not largely grown in cold frames, especially in our colder districts where it is a failure outdoors. It is a native of Algeria, and requires a hot, sunny position with not too rich a soil. When growing thriftily it usually blossoms profusely, and is then ideal for giving a supply of cut flowers. These are best cut when just opening. They develop perfectly indoors.

HOW TO EXCEL WITH ROSES

MR. GIFFARD WOOLLEY is to be congratulated on having written a really excellent little book* on Roses. In the short compass of 92 pages he gives chapters on the making and planting of rose gardens, including the preparation of the ground and the planting and after-care of the Roses; on pruning, on propagation, on Roses under glass and on exhibiting; also on the different classes of Roses and the purposes for which they are specially appropriate. There is a chapter which, alas! is a very necessary one, on "Rose Pests and How to Combat Them," and another on "Roses Under Glass." The remainder of the book is taken up with a list of the "Best Roses at Present in Commerce," and with a short but adequate Index.

The making of small rose gardens has at the moment very special interest. In driving about the country one is confronted everywhere with newly built houses, varying in size from the workman's cottage to the small villa in the garden city or the larger villa standing in, possibly, half an acre of its own grounds. The houses for the most part are not very beautiful, though they compare favourably in appearance with such houses built, say, fifty years ago; but they all have their little plot of ground, the development of which may be a source of much happiness and interest to their owners. A few hints as to how best to plan a little rose garden, therefore, are most timely. Mr. Giffard Woolley, in his chapter on "The Rose Garden" gives several plans suitable for really small gardens. The most satisfactory way to make a rose garden, whether large or small, is to cut beds or borders out of the turf, for nothing makes so good a setting for the brilliant and varying tints of Roses as grass. The garden should generally be somewhat formal and the beds large enough to hold at least nine to a dozen Roses; if possible, these should be all of one variety. Where the owner of the garden is anxious to have as little mowing as possible, he could not do better than copy the illustration (Fig. 2) of a garden of 24ft. in width which has two borders surrounding it with a break at each end admitting to a narrow path and small central bed. This garden, as Mr. Woolley suggests, could either have grass or stone paths. It is very simple, and it allows the cultivator to get at his Roses from either side. This is important, for Roses require a great deal of attention from the time when they are pruned in the spring right through the season. I am entirely in agreement with the author in recommending that bulbs should be planted between the Roses to give some bloom in spring, and that an edging of *Violas* is also a welcome addition to the rose garden. I know that many rosarians utterly condemn this practice. We have adopted it in our own garden for many years with some success, and I should be indeed sorry to see our numerous rose beds and borders devoid of flowers all through March, April and May, which they would be if no bulbs were allowed between them. In planting *Violas* among the Roses it is well to consider the colours, as they bloom at the same time. The soft mauve tints of *Maggie Mott* and *Kitty Bell* blend well with most Roses, but we have found that with the rather strong, crude crimson of some of the Polyantha Pompons a white or cream *Viola* is more harmonious.

In writing of the different classes of Roses, Mr. Woolley uses the expression "Butt-holed

Roses" where Decorative or Bedding Roses would, I think, better express his meaning.

The "Notes on Exhibiting" will be very useful to beginners (though the only way to learn to exhibit is to do it!) and also to those who, like myself, have been exhibiting decorative Roses for many years. Next summer I shall certainly try what to me is a new idea, namely, to leave the sprays of decorative Roses wrapped up in tissue paper till they are actually wanted for arrangement at the show rather than, as we have hitherto done, to unpack them all as quickly as possible and put them into water to wait till such time as we can give them attention.

A book on Roses is not complete without mention of the Rose species, which certainly in gardens of fair size are not only interesting and decorative, but also prolong the Rose season, for they usually are at their best in May, before the Teas and Hybrid Teas have come into flower. In the short chapter devoted to the species, Mr. Woolley does not include *R. rubra*, a delightful little sweet-scented variety from North America with shiny dark green leaves which in autumn change to brilliant scarlet and are followed by bright red berries. This is a dwarf variety and looks its best if the old wood is cut right away. *Rosa serotina* is a species well worth an isolated bed on the lawn, where its soft glaucous, almost downy foliage and tenderly tinted pale pink blossoms always call forth admiration. The foliage is specially lovely after rain; it seems to catch and retain the crystal raindrops in a way peculiar to itself. *Rosa rubella*, the crimson-fruited hybrid of *R. spinosissima*, makes a charming compact bush with abundant deep rosy flowers, which comes into bloom early in May and usually flowers again in the autumn.

There is one indispensable quality in the Rose which is hardly given so much prominence in this little book as it deserves. In the list of "best Roses," though fragrance is sometimes mentioned, it is omitted altogether in the description of such varieties as *Augustine Gumboussau*, *Hugh Dickson*, *Mrs. A. E. Coxhead* and *Zephyrine Drouhin*, whose attraction lies, surely, not least in their surpassingly sweet scent.

This little book is bound in white card-board, is well printed, is light to hold, and has several useful illustrations. Amateurs wishing to learn how to excel in Rose-growing will be well advised to invest half-a-crown in its purchase. WHITE LADY.

Answers to Correspondents

FLOWER GARDEN.

TREATMENT OF OLD LAVENDER HEDGE (Miss N. M. J.).—The only way to deal with the old plants is to cut back the branches as soon as possible to ensure new growth before winter comes. If this work is not done before the middle of September it would be advisable to leave the pruning back till late in March next. Cuttings will root in the autumn if inserted, with a small heel attached, in sandy soil made firm; or younger shoots in similar soil in frame in spring.

ROOF GARDEN.

PLANTS FOR ROOF GARDEN (Miss A. W.).—The Pansies that would do best in our correspondent's case would be those raised from seeds sown early in spring. The same applies in the case of *Violas*, but the following bedding-out varieties would succeed if planted in April: *Ardrie Grant*, indigo blue; *Bullion*, golden yellow; *Kitty Bell*, lavender; *Moseley Perfection*, bright yellow; and *Crimson Bedder*, a plumetum. *Saxifraga muscoides densa*, *S. m. Rhei superba*, *S. Rose Beauty*, *S. apiculata* and *S. Wallacei* would thrive. It is too late to sow Canterbury Bells for flowering well next year; purchase plants raised in June. *Auricularias* would succeed fairly well in the position referred to. The greatest general success would follow spring planting.

NAMES OF PLANTS.—J. S. Hayling Island.—The *Fedolium* is an abnormal form of *T. resupinatum*, due to the growing out of the inflorescence beyond the normal one.—J. M. D.—1. *Potentilla argyrophylla* Gilson; 2. *P. nevadensis*; 3. *Hypericum hookerianum*.—H. D. Ryde. *Genista tinctoria*.—W. S. M. 3. *Gaultheria shallon*; 4. *Prunus laurocerasus*, "Portugal Laurel"; 5. *Junus montana*; 1 and 2 not sent.

Garden Specialists, SOUTHWELL, NOTTS.

BARR'S Beautiful New Seedling NERINES

The most beautiful and easiest grown of Autumn-flowering Bulbs for the Greenhouse.

For autumn decoration in the greenhouse few plants can compare with Nerines for their brilliant and attractive colours. The flowers, produced in umbels of 6 to 24 blooms, are borne on stout stems from 1 to 2 feet high. The colours range from *dark red*, *vivid crimson*, *cerise* and *scarlet* to *salmon*, *coral-rose*, *pink*, *blush* and *white*, many having a glistening lustre which in sunlight gives them the appearance of being dusted with gold or silver. They remain decorative for many weeks, and their beauty may be enjoyed in a sitting-room as well as the greenhouse, if the pots are kept in a sunny window.

12 in 12 beautiful named varieties .. 42/-, 50/-, 63/- and 84/-
6 in 6 .. 18/-, 24/-, 30/- and 42/-
Mixed Hybrid Nerines (un-named) .. per doz. 25/-; each 2/6.

SPECIAL LIST ON APPLICATION.

No. 2705.—VOL. LXXXVII.]

[SEPTEMBER 22, 1923.]

FLOWERING CLIMBING PLANTS

C LIMBING plants which produce permanent effect are, in the nature of things, shrubby. Such an admirable climber as the Flame Flower, *Tropæolum speciosum*, while, under suitable climatic and other conditions, it renews itself each year, is unreliable for anything approaching permanent effect. The annual climbers of various kinds—*Tropæolum*, *Ipomœa* and so forth—are only mentioned here as being useful to fill gaps on house walls and such-like until the permanent kinds can make something of a show.

Few plants are more abused in the garden than these permanent climbers. How often does one see their tortured growths strained evenly over some monstrous "rustic" wooden erection which is enough in itself to send any sensitive person who had to live with it distracted! How frequently, too—though this is certainly a lesser evil—do we see climbers so "barbered" upon walls that they produce only a meagre show of blossom.

Excluding certain Roses—of which the beautiful Musk Rose, *Rosa moschata*, of which a form is illustrated below, is one—there can be no question that the most beautiful genus of really hardy British climbers is that of *Wistaria*. The growth of the plant, the grace of the hanging racemes in lilac mauve or white and the pleasing but comparatively scanty foliage, all make both the principal species—*sinensis* and *multijuga*—unrivalled for house walls or pergolas.

The genus *Clematis* must come a good second to the *Wistarias*, and here we have a wide selection for various purposes. For ample spaces on walls of no architectural beauty the forms of *C. montana* are ideal, while they are equally at home in the tree tops. The typical species flowers towards the end of May, while *C. montana rubens*, a variety with pinkish red new growth, purplish foliage and rosy red blossoms is a fortnight later. The variety *Wilsoni* with white blossoms rather larger than the type flowers in high summer. *C. montana rubens* is apt to be disappointing on red brick walls. It is admirable against stone or, of course out in the open garden.

Other vigorous climbing Clematises suitable for wandering over small trees or shrubs include *CC. Rehderiana*, *Vitalba* (Traveller's Joy), *orientalis* and, in favoured localities, *calycina* and *Armandi*.

C. Rehderiana, often listed and grown as *Clematis nutans*, has pinnate foliage of some size, each leaf usually consisting of from seven to nine leaflets. The flowers are primrose yellow and bell shaped with the points of the floral envelope (sepals in the *Clematis*) turned back for perhaps $\frac{1}{2}$ in. This is a beautiful but not showy species and the flowers are fragrant.

The Traveller's Joy needs no description, but it is a very useful and beautiful plant for the wild garden or the wilder parts of the pleasure grounds.

Clematis orientalis seems now to cover the plant long known in gardens as *C. graveolens*. Both the typical plant and the form known as *graveolens* have yellow flowers some 2 ins. across and produced in August and September, and pinnate foliage. *C. o. akebioides* (or better perhaps *C. glauca akebioides*) has blossoms deep orange yellow in colour and produced in October. This is a fine vigorous plant which should become popular.

Clematis calycina is an evergreen species which, except in favoured localities, should either have the shelter of a wall or a tree to itself on the western side of sheltered woodland. It flowers in midwinter, and the blossoms are yellowish white, spotted reddish purple. The foliage at the flowering season is very handsome, for it takes on bronzy purple tones in winter.

Clematis Armandi is another evergreen species also requiring shelter except in very favoured localities. The foliage is particularly substantial and handsome and the white blossoms are of some size (2 ins. to 2 $\frac{1}{2}$ ins. across) and produced in axillary clusters in April. This is one of the most striking new plants of recent introduction.

The large-flowered garden hybrid Clematises belonging to the Jack-mami, Lanuginose, Azure and Floride sections are also very charming rambling over large shrubs or in the branches of small trees. The variety illustrated on page 486, *Lady Lonsborough*, silvery grey in colour with paler bars, is a typical variety of the spring-blossoming Azure type and, like all the members of that section, should have a somewhat westerly exposure. The essential requirement for Clematises is shade for the roots and lower part of the growth. This applies to all except perhaps the forms of *C. montana*, which seem to succeed under almost any reasonable conditions of soil and climate.

Only by courtesy can the various species of *Ceanothus* be considered climbers, but many of them are only

A FINE FORM OF ROSA MOSCHATA, R. M. MACULATA.

hardy, especially in specially favoured districts against a wall, and they are well adapted for cultivation against house walls. *Ceanothus thyrsiflorus* (Californian Lilac), which is illustrated here, is mounted splendidly against a house, is quite one of the best for the purpose and, incidentally, one of the hardiest. The clustered blossoms are pale blue. The variety *griseus* has larger foliage and lilac flowers. Less hardy than the type, this too is splendid for a wall. The bright blue *C. Lobbianus*, often known as *dentatus* in gardens, is related to *thyrsiflorus*, being perhaps a hybrid between that species and the true *C. dentatus*. This latter has small, neat foliage and bright blue flower-heads; an excellent wall plant.

Ceanothus azureus, the parent of the splendid range of garden hybrids which includes *C. Gloire de Versailles*, forms a rounded deciduous bush about 6 ft. tall, but will grow taller on a wall. It is, however, hardy in dry situations in many English counties, and is most effective in the open. *Ceanothus rigidus* is a beautiful evergreen shrub with closely packed small foliage and deep purplish blue flowers. It is, unfortunately, very tender, and even against a house wall should be given a particularly sheltered corner. *C. Verticillatus* is probably a hybrid form, but, in any case, an interesting evergreen shrub with bright deep blue trusses of blossom. It is relatively hardy.

In a race consisting mainly of rampant herbaceous plants, *Polygonum baldschianicum* distinguishes itself as an admirable quick-growing shrubby climber which, when in flower, gives the effect of masses of white or palest pink foam. This is an invaluable plant where unsightly objects need covering quickly.

Honeysuckle everyone knows and nearly everyone grows, but the selection cultivated is usually unnecessarily meagre. The wild Honeysuckle of our hedgerows is *Lonicera Periclymenum*. Closely allied to it, but easily distinguished by the uppermost leaves being united at their bases to a stem-clasping cup, is *L. Capritolium*. It is equally as fragrant as *L. Periclymenum*. Later flowering is *L. etrusca*, which has more brightly coloured blossoms. This species, however, though quite hardy, is only really satisfactory outdoors in the South. *Lonicera italica*, said to be a natural hybrid between *L. Capritolium* and *L. etrusca*, is perhaps the most effective Honeysuckle we have. There are several excellent forms in cultivation, notably var. *atrosanguinea* with deep reddish purple flowers.

Of the forms of *Periclymenum* itself, the most notable are var. *belgica*, usually known as Dutch Honeysuckle, and var. *serotina*, valuable as an especially late and profuse flowerer.

Lonicera sempervirens (Trumpet Honeysuckle) stands outdoors only in favoured localities, but *L. Heckrottii*, *planchensis*, and *pumila* all feature it in habit and appearance. The flowers of all of them are bright pink to scarlet outside, yellow within and all three well worth growing.

Quite another race of Honeysuckles is typified by *L. japonica*, a strong growing evergreen climber with flowers red and white (var. *flexosa*) or white, changing to yellow (var. *Hidiana*). Variety *reticulata* with handsome foliage with the veins picked out in gold is more commonly grown than the others. The red or purple flowered species *Henryi*, *Gualteri* and *discolor* all belong to this section.

There are many forms of the tree-climbing Musk Rose, but unfortunately, some of them are not hardy. The one grown in *P. Brunoni* is the one generally cultivated outdoors, but *neapolensis* with pale yellow flowers and *P. ardens* with pink-tinged blossoms are quite distinct. The hybrid *The Garland* is also fine.

THE BLUE-FLOWERED "CALIFORNIAN LILAC," *CEANOTHUS THYRSIFLORUS*.

A BEAUTIFUL AZURE CLEMATIS—LADY LONDESBOROUGH.

THE HANDSOME *VITIS COIGNETIAE* ON A WALL AT GRAVETYE.

NOTES ON TULIPS

"R. S." ON TULIP SELECTIONS.

IN THE GARDEN for September 1, R. S. says my selections in the past were rather out of date (anachronistic is the word he uses), and my descriptions and remarks "wordy," quite, in fact, in the style of what *he* says of John Ruskin. What with one thing and another I am afraid he is hard to please and a bit like the "Three Young Maids of Lee," whose fate was sad like that of R. S., who has only left himself eight varieties wherewith to ornament his garden, *and one of these is too dear!!* and one is . . . !! etc., etc. I expect my selections in my article in the same number of THE GARDEN are just as bad as my old ones, and so I hope some one else will send some matter-of-fact lists with no verbal embellishments—no, not even use the word blue to trap the unwary, as R. S. himself might do! "La Fleur Merveilleuse" of Miguel Zamacois has sported and transformed itself into many strange colours and shapes, but, so far, it has not managed to appear in blue, or even anything admissible as blue.

AN OLD HINT AND A NEW MEANING.

I am very fond of turning over the pages of old gardening periodicals when I have an odd hour to spare. They almost always put a match to one's thoughts, and off one goes into visions of the past or daydreams of the future, or perhaps one gets a bit of interesting historical information, as, for example, that Cliveden was one of the gardens in which spring gardening was first instituted, or, it may be, we get a wrinkle of which one may make immediate use. A case in point occurred when I was recently turning over the pages of *The Florist, Fruitist and Garden Miscellany* for 1858. On p. 320 in the calendar for October, under the sub-heading of Tulips, we read: "The beds should be kept dry in readiness for planting early in November. Keep the soil frequently stirred to sweeten, *and see there is no green-fly on the bulbs.*" The italics are not in the original; they are now used because it is the green-fly note that I want to talk about. On more than one occasion within the last year suggestions have been made in the pages of THE GARDEN that there is some connexion between the "breaking" of Tulips and what is called mosaic disease. This is said to be conveyed from one plant to another by bites of insects, commonly if not exclusively; hence it would follow that if a garden or a field could be freed from those particular pests which delight in Tulip juice, we should probably never be worried with these unwelcome changes in the Tulip's wardrobe. A friend recently told me that infection could in all probability be conveyed from a dry bulb of which the flowers had become striped to the dry bulb of another which previously had only produced self-coloured flowers, and that, when next it bloomed, the flowers would be striped. This theory certainly sounds reasonable. Why should it not be so? If it is, *it behoves us to be very particular about the appearance of green-fly on our bulbs before they are planted.* Very likely others, like myself, have never thought much about it, except that the bulbs were made very sticky, and frequently, if not always, covered, when the skin was off or loose, with tiny red-looking dots. We must now be more particular and deal with the green-fly as we would do if the enemy were rats or mice.

Where the green-fly comes from, and how it comes are mysteries, but come it will almost certainly to any decent-sized collection of bulbs when they are stored in open trays or boxes previous to their being planted. All I can say is, we must be continually on the watch, for if the beasts have not arrived yesterday, they may come to-day and will certainly be with us to-morrow. Why was the

warning about green-fly given in *The Florist*? Was it a fortuitous anticipation? Now is it possible that there may be some connexion between the waywardness of the markings of broken Tulips and the infection conveyed by these insect bites? Generations of florists have wept over this inconsistency and have tried to overcome it. Sir Daniel Hall, in his introductory remarks in the R.H.S. Tulip Book, hits the nail on the head when he says (page 7). "Unfortunately, as yet, only a few varieties mark truly from year to year." Flies have in the past dealt (all unknown to anyone) death to horses and mankind; and they have been conquered. Now, Wisley, here's a chance for you

MAY-FLOWERING TULIPS AT SEDGWICK PARK.

to immortalise yourself by the unravelling of a problem which has been waiting for a solution ever since Western gardens received this great and glorious flower from the gorgeous parterres of Paradise and the East. Just think!! Clara Batts which never "break"; Annie McGregors which always feather; Samuel Barlows yearly richly pencilled with a brilliant red-brown; and Beau Brummell and Marksman for ever selfs. Tell us, Wisley, what "breaking" is. Tell us if the green-fly is a carrier of infection. If we knew, might not our day-dreams come true?

SOWING TULIP SEED.

As far as my experience goes, seed is best sown from August to October. I have sown in pans, in

loose soil in small cold frames, and in the open ground. I have never managed to have any success when I sowed in frames. Almost invariably "something happened, with the result that nothing happened." Never a solitary bulb did I secure. It was almost certain that it was the result of not giving proper ventilation or air that was the trouble.

In the open ground I make a channel an inch deep, the bottom of which I line with silver sand, as it is a great help in finding the tiny bulbs when they are lifted. Seed may be sown fairly thickly if the young seedlings are taken up the following June. This is always desirable, if it may not be called a necessity, because after the first year 90 per cent. will make droppers during their second year's growth. These droppers are the bugbear of the

seedling raiser, owing to the double difficulty of keeping them attached to the little parent, and also to the almost certainty of them getting mixed with one another if they are close together. This is why one-year-old bulbs should be lifted. I remember very well the late Mr. Walter Ware telling me what a job he had with his seedling beds in picking out all the bulbs of one kind. Droppers in either the second or third year were at the bottom of it. Hence, if seed be sown in 1923, the seedlings should be all lifted in 1924. It is then (1924) a question whether to plant them very thinly, say, 3 ins. or 4 ins. apart, again marking each bulb with silver sand; or putting each one in a small 3 in. pot and sinking the pot in the ground. Any dodge will do that will keep the parent bulb and its droppers together. The same principles hold good if seed be sown in pans. These should be placed in a cold frame of fair size, where plenty of air can be given. Both in the open and in pans a top dressing of fibre or something similar should be given to prevent the soil getting too severely

frosted. The young seedlings will stand some frost, but how much I do not know.

BAD SEEDS.

In the seed pods there are always, I find, a goodly number of husks mixed with the good seed. All should be carefully examined and, if there is any doubt, the seed in question should be held up to the light, when the flat opaque kernel is readily seen. I feel there is a very great future before those who raise hybrid Tulips. There are a great many species in addition to the huge number of those which are said to have come from *suaveolens* and the mythical *Gesneriana*. There is a great chance for a young and knowledgeable match-maker.

JOSEPH JACOB.

THE BEST LATE HEATHS

AMONG the Heathers which are in full bloom from about the first week in September (earlier in the South) I think *Erica ciliaris*, our own Dorset Heath, must be given first place. This, not only on account of its long spikes of very large bells in a cheerful rosy-lilac, but also because of

help-out the later days of summer with its whorls of pink and creamy-white, but the big, bushy masses of colour, which this species ultimately yields, one has learned to associate with the days of the retreating sun and we look to them to accompany the season to the brink of winter. The best varieties of *E. vagans* in general use are

THE WHITE CORNISH HEATH, *ERICA VAGANS ALBA*.

the beauty of its elegant and slightly downy, emerald green foliage which seems to have been especially designed by the god of gardens to entrap the first dew-heads of autumn and to present them to us in a setting of unsurpassed loveliness.

E. ciliaris is, perhaps, rather more impatient of drought than most of its kin. That is to say, it cannot be relied upon to do so well in such parched, sharply-drained loam as *E. cinerea* will put up with. It is also a trifle tender for a native, and dislikes wind. It may, nevertheless, be successfully grown in any average loam which suits other Heaths, given that little preferential treatment which it so richly deserves.

There is only one recognised native variety of *E. ciliaris* and that is the pure white form, a most exquisite thing. This is odd, since the Heaths indigenous to this country usually vary very considerably, giving us a wide range of colours. There is, of course, *E. Mawcana*, which is said to be a Portuguese form of *ciliaris*, a very handsome plant, but hardly, I think, so graceful in habit as our own. Then we have *E. Watsoni*, which claims *E. ciliaris* and *Tetralix* as its parents and which is a pretty, rather dwarf Heath which, with most commendable taste, displays the best qualities of both the species responsible for it. *E. Mackayi* also betrays no little suspicion of *ciliaris* blood, but opinions differ as to its origin. The clear rose and white blossoms of the double form of this variety are distinctly attractive and are usually to be found among the latest of our autumn-flowering *Ericas*.

The Cornish Heath (*E. vagans*) is essentially an autumn bloomer. True, it may often come in to

grandiflora, with long spikes in a full-toned rose-pink, and *rubra*, the flowers of which are of a deeper shade, approaching crimson. All forms of *vagans* have, however, been eclipsed by the variety known as *St. Keverne*, which, in addition to a constitution no less robust than that enjoyed by the type, has foliage of a rather darker green and enormous spikes of very large blossoms of a peculiarly attractive shade of salmon-rose. This will probably prove to be the most valuable hardy Heath introduced for many years.

In the *Calluna* group are several varieties which may be expected to flower well into October in many localities. The white, *Serlei*, is one of these, a very beautiful form with a free, branching habit and fine spikes of a good pure white. For some years this has held the field among others of its kind and colour, but, if report be true, *Serlei elatior*, which certainly promises favourably here, is likely to prove a serious rival to its original namesake. So it is, too, with that other and distinct white, known as *gracilis*. There is a new form of this offered which, in the length and elegance of its blossom sprays, no less than in its superior vigour, may mean the undoing of the older one. Of this, again, I only speak, however, from a comparatively brief experience.

Of the coloured varieties of *Calluna* which are still in full flower, and which will continue to be for some weeks, *C. vulgaris flore pleno* may be given premier place. This double Heath has the true colour of the moorland Ling at its best, that is, a fresh rosy-lilac, and since each blossom is perfectly double and very much larger than those of the single, the crowded spikes present a very

busy, well furnished appearance. This variety grows to about 3 ft. in height in good loam that is not too dry, the habit is open and eminently graceful and the flowering sprays are long and freely branched. It is, perhaps, not generally realised what a very attractive and long-lasting plant this double Heath can be when used as a cut flower for indoor decoration.

The deep crimson *C. v. var. Alportii* is also a late flowerer here, in some seasons not coming into full bloom until September, and the same may be said of the varieties *cuprea*, *argentea* and *aurea*, which, however, would not be worth growing were it not for their foliage.

Some young plants of the new *E. Williamsii* opened their first flowers the first week in September and they will doubtless be still giving colour when October is well in. This Heath is believed to be a natural hybrid between *EE. Tetralix* and *vagans* and was discovered growing at the Lizard by Mr. P. D. Williams. It has a strong leaning towards *Tetralix* in leafage and habit and its umbels of rosy-pink flowers are distinct and pretty.

The Corsican Heath (*E. stricta*) is in a class by itself, for not only is it the last to flower—often bridging the gap between the summer-autumn bloomers and the colouring of *darleyensis* which opens the winter season—but it is quite unlike any other Heath. Though a tall species, attaining a stature of 6 ft. to 7 ft., and reputed rather tender, it has stood some severe tests here without injury, and it is quite hardy at Kew. Perhaps the most noticeable feature of *E. stricta* is its foliage, which is of a peculiarly lively green and the leaves, being rather long and slender and closely set in whorls on the somewhat stiff, upright branches, give the shrub a curiously fuzzy appearance. The blossoms, borne in terminal umbels, are a vivid rose-pink. They usually appear at the end of September or early in October and continue, as I have said, almost into winter, when the dead corollas assume a warm, foxy brown tint which is by no means unattractive against the fresh green foliage. When it does well

and it will prosper in any warm loam that is lime-free—*E. stricta* will make a very desirable ornamental hedge that will be a pleasing object at any season.

N. WALES.

A FINE HYBRID BROOM

Away up on the slopes of the Maritime Alps, especially behind Mentone, there is found (although it is now extremely rare) a dwarf Broom known to botanists as *Cytisus Ardoini*. Its rarity is not due to any delicacy of constitution, but is said to be caused by the plants being eaten over by grazing animals before the seeds are able to ripen and scatter. However, it is now fairly well established in gardens, and as it grows only 4 inches or 5 inches high is admirably adapted for the rock garden, being covered with golden yellow flowers in April and May. Under cultivation it crosses readily with other Brooms, and at Kew about half a dozen hybrids have been raised, the best of which are *C. kewensis* and *C. Beanii*. The latter, obtained in 1900, appeared in a batch of seedlings of *C. Ardoini*, the other parent being undoubtedly *C. purgans*, a very handsome Broom about 3 feet high with deep golden yellow flowers. The hybrid grows from 12 inches to 18 inches high; its habit is semi-prostrate, a single plant becoming 3 feet to 4 feet across. In a young state especially it is very pleasing in its wealth of golden yellow flowers. It does not need a rich soil, and is easily increased by cuttings made in August and dibbled in under a bell-glass in some sheltered spot. *C. kewensis* is a quite prostrate Broom with creamy white flowers, raised from *C. Ardoini* and *C. albus*.

PERPETUAL-FLOWERING PINKS

PERPETUAL-FLOWERING Pinks may be divided broadly into two classes, classified by the Carnation Society as, respectively, *Herbertii* and *Allwoodii*.

The former are more upright in growth and have flowers of better quality, the latter are freer to flower. The *Herbertii* are most easily propagated by layering, the *Allwoodii* have only to be pulled apart. The cuttings will root even in the open border. Again, Mr. Herbert's Pinks favour the Border Carnation in that they like to settle down and establish themselves, whereas the product of Messrs. Allwood's Wivelsfield Nursery are short-lived unless divided, and on most soils are best divided up each year.

The first Perpetual Pink of the *Herbertii* strain was produced from a pod of seed of a laced pink called Arthur Brown, which had been fertilised with pollen from another laced variety named, if memory serves, Robert Houlgrave. If there was any Carnation blood in the variety, it is hard to see how it got there, and from this first perpetual variety, named Progress, we have now a whole series of fragrant, brightly coloured, handsome varieties. Theoretically at least, then, Mr. Herbert's varieties have no Carnation blood, whereas those of Messrs. Allwood are frankly Pink \times Carnation. Yet the *Herbertii* resemble the Carnation much more closely than do the *Allwoodii*, which, indeed, have some of the insouciance of the Indian Pinks in their make-up.

The weakness of Progress was its colour—a not too pleasing lilac-mauve with a purple zone. The failing of the first *Allwoodii* was in regard to form, which, from a florist's point of view,

was non-existent. The lapse of time, combined with careful work by the respective raisers, has given a variety of beautiful shades to the *Herbertii*, and has improved almost beyond belief the form and texture of the *Allwoodii*—yet the two plants remain entirely distinct.

The *Allwoodii* are still, primarily, plants for massing, though the last of them are quite charming for indoor decoration. They lack, however, the dignity of Mr. Herbert's varieties, for these last have, in the writer's opinion, the touch of quality which no fancier's laced Pink ever possessed.

Not everyone will agree as to what places a flower in that small but select class which includes the best Lilies and Roses. Some of the best and most richly coloured of the Bearded Irises would surely be eligible to enter. *Iris sibirica*, *I. unguicularis*, some of the *Kempferi* and English Irises and quite a number of other *Iris* species might also be included, so might the Snakeshead, *Fritillaria Meleagris* (alone of its family), and among *Gladioli*, *G. primulinus* and the best of its hybrids, *G. tristis* and the better *Colvilei* forms and hybrids, and the Carnation. Those to whom the foregoing represent the veritable aristocrats of the plant-world will gladly welcome—if and when they know them—Mr. Herbert's Pinks to the select company.

There are those who prefer the Delphinium to the Lily, the Lupin to the Iris; not, be it noted, as effective border plants, but as flowers—for themselves alone. They, naturally, may not place these Pinks upon so high a plane. Everything, after all, depends upon the point of view. Messrs. Allwood's productions cannot aspire to

inclusion with stars of the first magnitude. They are but work-a-day garden flowers, as suitable for the backyard of a London "semi-detached" as for the garden of broad acres, and out of place in neither. Being for the most part of a dwarf and not too diffuse habit of growth, they make capital edging plants.

It is unnecessary to dwell upon the cultivation of either strain. The secret of success with *Allwoodii* is to divide them frequently and to procure good sturdy plants in the first instance. Some of the stuff offered nowadays at very low prices has had its constitution destroyed by propagation in high temperatures, often from unsuitable stock. The *Herbertii* succeed best when treated precisely as one would treat Border Carnations. They may be planted out in spring or in autumn. Autumn planting is good on soils where young Carnations winter well, otherwise spring planting is desirable. A thoroughly well cultivated, well enriched soil, but sweet withal and with a fair percentage of lime, is ideal for them. They may, of course, be grown under glass just as the fanciers cultivate the Border Carnation.

Now as to varieties. The following are a few of the very best *Herbertii* to date. In crimsons we have The Imp, black-crimson, and Victory, bright rich crimson. Both have fully double, well poised flowers, and both are delightfully fragrant; the blossoms are of useful size, but small compared with some of the giants in pink and rose shades. The best pink varieties to date are Bridesmaid, Mrs. Giffard Woolley, Queen Mary, Mrs. G. Walker, May Queen and Model. All these have something in common, yet all are absolutely distinct. Model is remarkable for perfection of form judged from a florist's

DELICATE 'ALMONY BLUSH'; DIANTHUS (HERBERTII) BRIDESMAID.

THE BRIGHTLY COLOURED DIANTHUS (HERBERTII) FIRE KING.

THE STRAWBERRY TREES

standpoint—the colouring is soft rose pink with a deep red base. Bridesmaid is a much larger flower, but lightly built and of a delicate salmon flesh tone with deeper colouring at the base. Queen Mary and Mrs. G. Walker, though different in appearance, are both rose pinks, without any hint of mauve and with richer colouring at the base. May Queen is a bright pink self. These last three are all of large size. Mrs. Cardinal Woolley is a very large fully double flower of the colouring of Enchantress Supreme Carnation, but with a deeper tone of colour at the base which, owing to the fullness of the flower is hardly seen, but which serves to give an effect of solidity and to redeem the general colouring from any suggestion of insipidity.

In other tones of colour there are Negress, rich plum colour; Comedy, rosy mauve with deeper base—an improved Progress; Simplicity, cherry red with dark base markings; Red Indian, of deep rosy lavender shading; Fire King, a brilliant cerise with deeper base colouring; and Lord Lambourne, of a velvety carmine tone and of great size.

The recent improvement in *Allwoodii* has been, as previously noted, considerable. One of the most notable of these new varieties is the rich crimson purple Hugh, a self-coloured flower of good form and well carried. The deep salmon rose Marion, the pretty shrimp pink Joyce, the pale salmon self-coloured Lottie and, above all, the semi-double, nicely shaped Sybil with delicate flesh pink blossoms are noteworthy among pink shades. Alfred is the best pure white to date. [It may be mentioned that there is, as yet, no pure white *Herbertii*.] Barbara, a new fringed crimson, is an excellent doer and of good habit. These are only a few selected from a range of about forty varieties, a good number of which have “contrasty” flowers in white or some pale shade and maroon.

It is quite safe to say that neither *Herbertii* nor *Allwoodii* are used in gardens to anything like the extent which their merits deserve. As far as Mr. Herbert's Pinks are concerned, they do not seem nearly as well known as they should be; while cheap, spoiled stocks of *Allwoodii* have, in some quarters, hindered the popularity of the flower.

CORNUS KOUSA

There is a remarkable, if not very large, group of Cornels represented in gardens by this species, *C. Nuttallii*, *C. florida* and *C. capitata*, the beauty of the inflorescence of which is imparted by four or more large bracts, not by the flowers themselves. Of these Cornels, the one most amenable to cultivation is the Japanese species *Cornus Kousa*. The real flowers are very tiny and crowded into small dark cones, each of which is surrounded by four beautiful spreading bracts. Each bract is 1 inch to 1½ inches long, and creamy white. This devious small tree or shrub is at its best in June, when the inflorescences (“flowers” one usually terms them) are fully expanded and stand erect in rows along the branches. It then presents an aspect of striking beauty. The fruit is a fleshy strawberry-like mass in which the seeds are embedded, and is really a development of the little cone on which the flowers are set. The leaves are about 3 inches long, with undulated margins and conspicuous parallel veins. The real drawback to the success of this Cornel in gardens is the mild, soft weather, of which our normal winters contain so much. The tree is thereby often excited into prematurely active growth, only to be injured by later frost. Otherwise it is very hardy. It thrives best in rather elevated districts. Young plants are usually imported from Japan

THE most familiar of that small group of Ericaceous plants known as the Strawberry Trees is *Arbutus Unedo*, a native of the Mediterranean coasts and of the extreme south-west of Ireland. This handsome evergreen is the hardiest of its kind, and one that will attain a height of 30 ft.

as those of *A. Unedo*, the greenish white blossoms being followed by fruits which are barely ½ in. in diameter and of a bright orange. The most remarkable feature, however, of this species is the bark, which is a bright lettuce green on the young wood and a warm cinnamon brown on the old. Every autumn this bark sheds its skin, this peeling off

A SPRAY OF *ARBUTUS UNEDO* AT THIS SEASON.

and more almost anywhere in our more genial counties. The leaves of *A. Unedo* are strong and leathery, narrowly oval, finely indented and of a rich glossy green. The young shoots, which are hairy, are usually tinted with red, as are the mid-ribs and stems of the leaves, and the rough bark, especially in old trees, is a rusty brown.

It is in mid-autumn that *A. Unedo* appears at its best, for then the large, strawberry-like fruits of the previous autumn's flowers assume their well known orange and crimson colours, and the tree is at the same time bearing its crop of blossom for fruiting the succeeding year. These blossoms are borne in loose, drooping panicles about 3 ins. long, the individual flowers being pitcher-shaped and of an ivory white which is sometimes shaded with pink. There are several forms of *A. Unedo*, the variety *rubra*, with rosy flowers and a dwarf, bush-like habit, being one of the most distinct.

The much more uncommon *A. Menziesii* (procera) introduced from California by Douglas over a century ago is a still more beautiful tree than the above. It must, indeed, be regarded as quite the best of the genus, and one of the most distinctive and attractive trees of the Heath family. In this country it attains about the same stature as *A. Unedo*, but it is a faster grower and, being rather more tender, its unripened tips are apt to be injured by frost and cold winds save in our westerly counties.

A. Menziesii differs from the commoner species in having longer and broader leaves, and these are a fresher, more highly glossed green, while their undersides are distinctly glaucous. The flowers are borne in spring in pendulous, terminal clusters, which are three or four times as large

in thin rolls, leaving the trunk of the tree and main branches so smooth and clean that they look as if they had been modelled in terra-cotta.

A. Menziesii, the Madroña of the Pacific Slope of North America, grows abundantly not only in the fertile inland valleys of California, but on the rocky cliffs and islands of the northerly parts of that State and into Oregon and British Columbia. There, where the trees get little shelter from ocean winds, they often assume extraordinary shapes, the thick stems being quite out of proportion to the umbrella-shaped heads or to the strangely distorted branches, of which the padded foliage looks as if it had been swept all one way by some persistent wind—which is in reality precisely what has happened to it.

A. Andrachne is a native of South-East Europe, and it is usually seen as a good-sized, spreading shrub some 10 ft. in height. This species comes nearer to *A. Unedo* than the foregoing, but may be distinguished from it by the smoother fruits and rather broader leaves which, when fully grown, have untoothed margins. As I have indicated, *A. Andrachne* is also of a more compact habit than either of the other species mentioned.

Midway between *AA. Andrachne* and *Unedo* comes the well known offspring of these two *A. hybrida* (*andrachnoides*). This is an extremely variable shrub, or small tree, since it may possess a fair share of the principal features of both its parents or bear a much closer resemblance either to one or the other. Generally speaking, the medium-sized leaves are slightly glaucous beneath and indented at the margins. The white flowers, borne in terminal panicles and pitcher-shaped like those of the others, are produced in autumn

or spring, sometimes at both those seasons, and the globular fruits are somewhat like those of *A. Unedo*, but hardly so rough.

Those I have mentioned are the only members of the genus *Arbutus* that can safely be considered

hardy enough for outdoor culture in the milder regions of this country. They are good seaside plants, but do better in sheltered valleys within the sea influence. All will prosper in any well drained loam. They are good drought resisters,

and one of them at least, viz., *A. Unedo*, will grow in limy soil. There is a Chilean species, *A. furcans*, with bristly leaves and wine red fruits, which is said to be hardy in the most favoured parts of the south-west. J.

DECORATIVE DAHLIAS

ALL good Dahlias, no doubt, are decorative, except the exhibition Cactus sorts and, perhaps, the old-fashioned Show and Fancy varieties, though even these are usually decorative enough in the garden. Technically speaking, however, "Decorative" as applied to a Dahlia bears a special meaning. All those double Dahlias which have neither the globular form of the Show Dahlia nor the spidery loveliness of the Cactus type were formerly lumped together as Decorative. In practice, however, the Decorative Dahlia has evolved a form of its own, a form well shewn by the pictures below and which was originally made noteworthy by that huge and brilliant garden variety *Souvenir de Gustav Douzan*.

The National Dahlia Society decided last year—very wisely so most people will think—to make a separate classification for the smaller Decoratives of the type which are now very aptly called Camellia-flowered. Both the large Decoratives and those composing this new class are almost purely garden Dahlias, though either may be used effectively for filling large vases in halls or elsewhere.

At first sight it is not obvious why these Decorative and Camellia-flowered varieties should so

outweigh the Cactus, Show and even Peony-flowered types in the garden. One has only to see them side by side, however, at once to realise the difference. Most of the Cactus-flowered varieties absolutely hide the blossoms in the foliage. The Peony-flowered certainly carry their flowers higher, but these are weak-necked and "shy," and though very useful for some purposes, they never give the bold colour effects afforded by the Decorative varieties.

Both classes of Decoratives are largely used nowadays in public parks and gardens throughout the country, and the attention which these displays receive from amateur gardeners of all classes must make for their extended popularity.

The two brand-new Decoratives illustrated herewith are both novelties of Messrs. Stredwick and Son, St. Leonards, famous the world over for their splendid Cactus varieties. Both hold their flowers rigidly parallel to the stiff, tall stems. Mrs. E. G. Cant has blooms of a soft yet bright yellow and some 7 ins. or 8 ins. across. Gloria is bright crimson—almost scarlet crimson—and the flowers are of immense size; the colouring is richer but less penetrating than that of that "father" of present-day Decoratives, *Souvenir de*

Gustav Douzan. A few other excellent large Decoratives of this type include Mrs. Sturdy, yellow, shaded amber; Lady Seeley, coppery orange; H. C. Drussellius, pink; Hon. Mrs. Clive Pearson, scarlet; Kingswood Beauty, pale primrose yellow; Dragoon, crimson; Yellow Colosse, deep yellow; and Orange King, deep orange. Brentwood Yellow, a most excellent dwarf bedding variety, is rather different in type.

Of the Camellia-flowered class the outstanding variety is undoubtedly *Crimson Flag*, which probably shares with that dazzling Mignon variety *Coltness Gem* the distinction of being the most popular Dahlia at the moment. Other good ones are *Reginald Cory*, crimson, tipped white; *Barlow's Bedder*, scarlet; *Cheal's White*, pure white; and *Dobbie's Bedder*, creamy yellow.

These Decorative Dahlias, however described, may be used advantageously in association with the single forms classed as "Stars" and with the no less useful Mignon Dahlias which might almost be called compact-habited Stars. Even the more free-flowering exhibition singles are useful with these Decoratives. An excellent colour combination is the Camellia-flowered *Crimson Flag* used with the yellow Mignon Dahlia *Pembroke*.

RICH CRIMSON DECORATIVE DAHLIA GLORIA.

GLASGOW GREAT SHOW

GLASGOW again—it seems but a few weeks since we were all here last year admiring the great International Flower Show, organised and carried to a successful issue by that model public body, the Glasgow Corporation, an incorporation, indeed, of enterprise and "go." The present display, too, had the imprint of success all over it and it is safe to predict that the Second City has now settled down to an annual floral fête of great dimensions.

As was so last year, what might be termed the city's own exhibit was a leading feature of the Show. Mr. E. Matthews, the Director of Parks, gave free scope to his powers in arranging a 300ft. double border along the main avenue of Kelvin Hall. The pathway between the borders ran under an imposing length of pergola clothed with scandent Roses and other plants, and half-way down its length was placed a sundial, very neat in design. The borders themselves, backed by specimen shrubs in almost endless variety, were ablaze with colour, in which flowers of all the summer weeks were represented—Poppies, Delphiniums, Pentstemons, Astilbes, Hollyhocks, Nicotianas, Heaths, Sunflowers and Michaelmas Daisies well to the fore. Terminating this long vista was a large circular pond animated by many fountain jets and beautifully lit up at night with numerous tiny coloured electric lamps.

Two hundred years of business have not staled the efforts of Messrs. Austin and McAslan, the oldest firm of seed-men and nurserymen in Britain. No fewer than four separate exhibits were staged by them. Close to the main entrance they had a very extensive show of vegetables, as well grown as any we have seen this season, and, to amehorate the severity and utilitarian aspect of the stand, it was backed by numerous spikes of very lovely Gladioli in tall vases. Further on they had a large group of young trees, including some nice specimen samples of *Abies pungens glauca*, *Cedrus atlantica glauca*, *Retinosporas* and *Andromedas*. Some very prim and proper looking examples of clever topiary work were also shewn. This versatile Glasgow firm staged Roses, too, and Roses grown in such a way as to give the impression that these flowers were the main motif of the business. Their fourth space was taken up by garden sundries and apriary appliances.

Messrs. Dobbie and Co. of Edinburgh did not disappoint those who look for great things from the "east-windy, west-endy" city. Over a length of 90ft. of staging were banked magnificent drifts of Roses, Sweet Peas, Dahlias and other flowers of summer and autumn. The Sweet Peas were a feast for the eye of the epicure, and however bad the summer may have been in the North, the climate most certainly paints the Sweet Pea with a freshness and delicacy of beauty seldom seen in the South. The Roses, too, were remarkable for their high colour and freshness, most notably Queen Alexandra Rose and Betty Uprichard.

The best floor group, which gained the Corporation's cup and a very generous first prize in cash for a display of stove and greenhouse plants, was arranged by Mr. W. A. Holmes of Chesterfield, second and third places being secured by Mr. J. M. Patch of Bradford, and the head gardener to Mr. W. H. Gads, of Paisley.

Messrs. Russell of Richmond staged a splendid group of hot-house plants, including a specimen of *Aristolochia Sturtevantii*, that weird looking and monstrous flower which attracted a lot of attention last year at Vincent Square. The bloom is some 10ins. long by 5ins. wide and apart from its rich, but sombre colouring, its chief function seems

to be the distribution of a powerfully offensive odour.

Phloxes and Pentstemons in well arranged groups made up the bulk of Messrs. Forbes big display from Hawick, some of the most notable of the Phloxes being Marvel (blue), Eliz. Campbell (salmon), Minerva (pink), and Ringstroom (crimson).

Alongside, Messrs. Lowe and Gibson had a splendid assortment of their well known Gladioli, including many spikes of their own pedigree seedlings. This group was tastefully arranged with Ferns in variety, placed among the flower vases.

From Merstham, Messrs. Wells took a well selected lot of herbaceous plants which made up a fine colour effect.

A noted Scottish firm, Messrs. Thyne and Son of Dundee, had a most tastefully arranged group of hardy plants with the colours shrewdly placed to best advantage.

Carnations are always a strong feature at this Show, even the Border varieties, long since past their best in Southern parts, were shown in their prime. Messrs. Engleman had the best group of Perpetuals, and Messrs. Torrance and Hopkins staged the most beautiful group of "Borders" we have seen for a long time. In the competitive classes for the same flowers many exquisite blooms were staged, the new yellow variety, Mary Murray, taking a very prominent place. White Fox was also shown in perfection.

Very restful to the eye is a stand such as Messrs. Ellison's of West Bromwich put up, composed to a large extent of Ferns and Palms, with a beautiful bordering of *Saxifraga sarmentosa tricolor*. Over a hundred varieties of exotic Ferns were employed.

One of the most popular stagings in the hall was that of Messrs. Blackmore and Langdon, who shewed Begonias and Delphiniums in their own peculiarly thorough fashion. The pure colour tones of the huge Begonias appealed strongly to visitors, especially varieties such as Queen of the Belgians (pink), General Joffre (brilliant scarlet), Mrs. W. L. Ainslie (rich yellow), Lucy V. Toner (rose), and Lord Lambourne (apricot).

A word must be said about the competitive classes of cut flowers which were of the highest

excellence. In the Gladioli classes Messrs. Mair of Prestwick shewed enormous spikes of bloom of the highest quality. Another Prestwick exhibitor, Mr. Wm. Rae, had entries of almost equal excellence, shewing that the mild and damp atmosphere of the Ayrshire coast, coupled with its sandy soil, provides ideal conditions for the growth of these irids. One of the classes in Gladioli was led by Mr. D. Whitelaw of Laureneekirk, and these particular spikes were the best in the Show and were actually the grandest specimens that ever came under our notice.

The Border Carnation classes also brought out some exceptionally well grown flowers, particularly those of Mr. Wm. Muir of Darvel, Mrs. Smith of the same town, and Mr. David Carlaw of Glasgow.

The Sweet Peas shewn in the competitive classes were the best we have seen this season, the high colours being extremely bright and the more delicate tones so fresh and dainty that we must frankly admit the fact that Scottish-grown Sweet Peas are equal at least to any the world produces.

Some representative groups of fruit were staged, but though the entries for decorated fruit tables, which were really a handsome feature of the Show, contained many perfect samples of high-class products, they were obviously hot-house grown, and the general results obtained from orchards shew the disadvantage of the less sunny climate than that enjoyed by the large English fruit growers.

A CHARMING ANDROSACE

ONE of the most easily grown and most charming of Androsaces is *A. lactea*. Its glossy, dark green mats of foliage fear neither fog nor winter wet and its pearly-white blossoms are lightly and informally arranged in the looses of corymbs. This Androsace (to shew the scale of a picture), generally attains a height of from 7ins. to 10ins. to the topmost blossoms. Although it belongs to the same section as *A. carnea*, this species is not a peat-lover, indeed, it is rather partial to lime, but always succeeds in the sunny moraine or even in a deeply cultivated stony pocket. It must not be confused with the annual (or biennial) *A. lactiflora*.

THE PEARLY WHITE ANDROSACE LACTEA.

CORRESPONDENCE

A FINE PLANT OF THALICTRUM DIPTEROCARPUM.

IT may be interesting to record that I have grown a plant of *Thalictrum dipterocarpum* in my garden here which has attained a height of 7ft. 10ins. I have enquired of many professional gardeners and none has been able to say that he has seen or heard of one reaching such a height, which seems to shew that it is unusual. The previous year I had one that grew to 5ft. 10ins., but others have not exceeded 2ft. to 3ft. I am enclosing a photograph.—Jno. F. E. CUDMORE, *Ingham, Lincoln.*

[Unfortunately the photograph is unsuitable for reproduction.—ED.]

THE CULTIVATION OF STRAWBERRIES.

SO the "great Strawberry controversy" has started again. May I explain my method, which I have found very successful over a number of years. Runners are taken from one year old plants during mid-June and pegged into "60's," these plants are also carrying a heavy crop of fruit, but I never have any difficulty of finding runners nor are they in any way deficient in strength. Beyond rain, no water is given; they are cut off about mid-July, stand on boards and are well watered until the first week in August, when they are planted out at a distance of 2ft. 6ins. between the rows and 1ft. between the plants in the rows. After the first crop of fruit is taken off, each alternate plant in the rows is cut out, and the remainder stay for two more seasons, three in all. I find it pays to keep them three years, as by this method the season is greatly prolonged. The one year old plants fruit from seven to ten days before the two year olds, which in their turn beat the three year olds by three or four days. As for being worn out, this season I counted six average plants, each of which had well over 250 fruits on, and this was on three year old stools. Also, by taking runners off one year old fruiting crowns, I do not have to find room for a lot of plants grown specially for runners. In regard to quality, we have picked fruit up to 3oz. in weight without any thinning. I do not suppose these few remarks will cause the Rev. Engleheart to alter his procedure, but I do claim to get both good fruit and good runners off the same plants, where he grows two lots of plants for the same end.—W. P. WOOD, *Benington Lordship, Herts.*

[No doubt different soils and climatic conditions—to say nothing of varieties—make an appreciable difference to the production of Strawberry runners, but those gardeners who find a difficulty in getting good, early runners, and there are many such, should adopt Rev. G. H. Engleheart's method of growing maiden plants especially for runner production.—ED.]

ABOUT ALPINE LILIES.

ALLOW me to add a few words to the lines of Mr. Hadden in *THE GARDEN* for Sept. 8, page 470. *Lilium pomponium* is really such a beauty that no one can resist its charm when seen in the natural state. I set out my views on the matter on a previous occasion (*THE GARDEN*, December 30, 1922). Since last year, however, I am able to state the great distribution of the plant in the eastern parts of the Maritime Alps, and particularly about the Roya Valley. As Mr. Hadden says, the Lily grows plentifully about St. Martin Vesubie. There, however, it grows as a rule on inaccessible rocks, and its bulbs are deep down among the stones and difficult to get out. If one would exercise the necessary patience to get any, one must be prepared to spend hours and hours about

it. If, on the other hand, one commissions the inhabitants or peasants to send some when the bulbs are ripe, they send on *Lilium croceum* instead of the right plant. This I found out by sad

GENTIANA FARRERI GROWING ALMOST LIKE A WEED.

experience last year, and I am in some doubt whether we sent out to all our customers the right species. Certainly some of those I procured in this way proved wrong when they flowered in the nursery. In order to get it true, it is therefore necessary to go there and to dig it up oneself. Last summer we found in some valleys at a considerable elevation in the Roya region, large fields of the right species, and the plants there were much better than in the Var Valley. Some of them bore seven flowers on the stem! They grow there under quite dissimilar conditions to those in the western part of the Alps. They spring up among the grass on very steep slopes and seem to flourish the more the steeper the slope. I was surprised to note this, because *L. carnioleum*, which is very near to *pomponium*, grows—at least as I have seen it—in flat meadows. Here, in the Roya district, *pomponium* is only found on precipitous slopes and deep in the soil, but it is easier to lift than in the rocky slopes of the Var Valley. I know, of course, that it is very abundant on the tops of the mountains above Grasse and Nice, but there, too, it is difficult to get. A very curious station for it is at 6 kilometres from Nice in the Val Roguet (an extraordinary place hollowed by the water through the rocks), where our Lily hangs from the cliff in quite inaccessible places. Now that I have seen the rich meadows of the Roya Valley—they are easy to reach from

Fontan—I think that *Lilium pomponium* should be grown, as Mr. Dillistone says, in shady places; or that, at least, the bulbs of it should be in shade. The thick grass there covers all the lower part of the plants, and it is certainly the reason for their luxuriance. May I add that in some woods of the little Rattery Valley above Colmars-des-Alpes I found fields of the common Martagon with nearly a hundred flowers! There are places where that species forms dense colouring and is the only plant covering the ground. These places are an hour's journey from Colmars and in the re-afforested area on slopes which were, fifty years ago, barren and as dry as the desert. The re-afforestation of the country and the prohibition of grazing—no goats or sheep may be grazed there—produced this beautiful result!—H. CORREYON, *Geneva.*

A FINE BATCH OF GENTIANA FARRERI.

I ENCLOSE two photographs shewing *Gentiana Farreri* growing in my garden at Glendevon, Perthshire. The *Lilium* growing behind the *Gentiana* is *philippinense* var. *formosanum*. These *Gentianas* were raised from seed three years ago; you will see the plants have made good growth. I think one reason some people have difficulty in growing *G. Farreri* is that their plants have been propagated from cuttings; such plants are not nearly so healthy as those raised

from seed. My plants ripen seed every year, which, if sown in the spring and planted out in July, flower the following year.—A. H.

[The picture not given herewith shewed a considerably greater number of plants, but was less suitable for reproduction.—ED.]

ROSE BETTY UPRICHARD.

IN the south-west of Scotland this lovely Rose has done well this season, and has been much favoured wherever seen. It is one of those which looks as if it might hold its ground when many others have passed into oblivion. Its glorious flowers of vivid carmine and orange have been very good indeed.—S. A.

THE OLYMPIAN MULLEIN.

SEVEN to eight feet branched spikes of that giant Mullein, *Verbascum olympicum*, are most effective in a flower garden, especially when seen against a background of taller-growing shrubs. We have it here against some *Bambusos*. Ordinary unmanured ground suits this *Verbascum* well, while such positions as open spaces between shrubs or sunny sites in the woodland offer happy stations for its home. In addition to its noble flower head, this plant, in its young stage, has a handsome rosette of greyish-green leaves. As it often runs into the third year before some of the roots flower,

seedlings. It did be encouraged to follow on regularly in succession, to avoid gaps in the display. As good a way as any to do this is to let a plant or two ripen and disperse its seed, afterwards transplanting the plants where required. A near relative of this Mullein is *Celsia cretica* (the Cretan Mullein), also a splendid border or shrubby plant, but *V. olympicum* bears larger flowers of a deeper shade of yellow and an imposing branched inflorescence, as against the single 4ft. spike or so of the *Celsia*. C. TURNER, *Amphill Park Gardens, Amphill*.

A PERGOLA AT GRAVETYE.

PERGOLAS are often erected without any justification and which lead nowhere in particular; indeed after traversing them, one often comes to a dead end, which is, to say the least, disappointing. So important and, if properly designed, so beautiful a structure should either lead to a beautiful view, to place of rest or, best of all, to some feature of architectural interest. The pergola of which I send a picture, after ascending a flight of steps from the stone-paved flower garden, leads along a paved pathway to the bowling green. Modest in design—the pillars being of brick and the bearings and battens of oak—it has the pillars and also the retaining wall at the upper end which supports an intersecting path coming from the opposite direction, whitened. When the climbers are in full leaf the whitened pillars have a pleasing effect. The Japanese Wistaria, Roses, Clematises, Honey-suckles and Climbing Knot Weed (*Polygonum baldschuanicum*), are its chief occupants. The flight of steps in the foreground is planted with Dwarf Phloxes, Gypsophilas, Harebells, Thrift, Bell Gentians, Thymes, the silvery Lavender Cotton (*Santolina Chamæcyparissus squarrosa*) and that indispensable little New Zealander, *Helichrysum bellidioides*. Along the sides the snake-like growths of *Tropæolum polyphyllum* are falling over the foot-high stones which support the higher ground. No special preparation was made for the plants which are seen in the steps; the flagstones were slightly raised and the roots just pushed under them. E. MARKHAM.

[The whitening of the piers at Gravetye is justified on the score of lighting. It is not usually necessary. ED.]

THE "VIOLETTAS."

AS one who had some correspondence with the late Dr. Charles Stuart, of Chirnside, the raiser of the original *Viola* called *Violetta*, and though having from time to time been sent by him blooms of his newer varieties, I have been long interested

in the *Violettas*. They seem to be going largely out of fashion, their place being taken by some of the less formal *Violas*, such as the *gracilis* varieties and hybrids. Yet it would be a pity were the *Violettas* lost sight of. Mr. Crane used to keep a good variety, but one may look through a considerable number of catalogues without finding even the name of the first and, still in my estimation, the best, the original *Violetta*. I was struck by this after seeing a lovely bed filled with it as a carpeter for China Roses in a pretty garden I visited the other day. To those who know it not I may say that *Violetta* is a miniature *Viola* of perfect form and of a delightful creamy-white and possessing a distinct and delightful perfume. It is a free grower and a gem for the rock garden, edgings or small beds. The other varieties, of which there were all colours in the gamut of colouring in the *Viola* race, were excellent also, yet, as already indicated, I do not consider them of

FROM FLOWER GARDEN TO BOWLING GREEN.

equal value to *Violetta* itself. It is as easily grown as any border *Viola*.—S. ARNOTT.

ANEMONE CYLINDRICA.

SHOULD anyone see *Anemone cylindrica* offered in any list, I would advise them to pass it by on the other side. It is a worthless thing, with long stems and cylindrical-shaped flowers of a dull greenish white. It is the poorest plant that I know among the Windflowers. I once obtained it many years ago as a novelty and grew it for a few seasons hoping against hope that it might improve as it became larger, but it had ultimately to be discarded as a plant not worth its room. I see that the late Mr. Reginald Farrer had a similar opinion of it. S.

STORING HARDY FRUITS

HARDY fruits are not as plentiful this year as last, with possible exceptions in some districts in certain counties. Naturally, more care will be taken in the manner of storing. In seasons of plenty, unfortunately, there is much wasted fruit in this country, which should not be. Only scarcity seems to have the effect of making cultivators appreciate the value of good Apples and Pears during the winter and early spring months.

These notes are not written for the benefit of experienced cultivators, who also possess ideal fruit-rooms, but for amateurs who have not had much experience and do not possess specially-built structures.

The proper gathering of the fruits has a direct bearing on their keeping properties. If gathered before they are ripe, there is too much shrivelling when the sugar in them begins to coagulate; this condition is best brought about to a considerable extent while the fruits are on the trees. Take, for example, fruits of Cox's Orange Pippin; those gathered before they readily part from the branches rarely keep fresh longer than Christmas. Probably this premature gathering is mainly responsible for the fact that tons of Cox's are regarded as being past their season at Christmas. A very large retail and wholesale dealer once told the writer that Cox's were, practically speaking, over by that date, yet I have had no difficulty in storing the fruits in nice fresh condition till March, and there are many other growers who also succeed in doing so. I like to leave the Apples on the branches till they part from them with a very light pressure and it is this late gathering that has such a beneficial effect on their keeping properties.

In the case of Pears, these fruits should part readily from the stem or branch when gently raised to a horizontal position. Furthermore, the very careful handling of the individual fruits at all stages is very essential to their good keeping.

The storeroom is, generally speaking, only partly devoted to fruits; it is exceptional for it to be wholly given up to them. In any case the place must be clean, dry and cool, but frostproof. All fruits should be laid in single layers on shelves, or in shallow wooden trays. Painted shelves are neither necessary nor desirable; unpainted, clean, open-lathed ones are the best. I do not use straw when such shelves are available. The fruits should not be wiped. They should be placed very gently on the shelves—the Apples in the coolest part of the room and the Pears in the warmest, if there is any difference in this respect. Very close inspection at storing time, and once weekly afterwards to detect and remove any specimens shewing signs of decay, must be the rule to prevent more than the absolute minimum of loss. Ventilators, low down, provided with perforated zinc sheeting if possible, and half the amount of these inlets just above the highest layer of fruits, will ensure perfect ventilation. A skylight may be useful occasionally, but is not absolutely necessary.

Storing under primitive conditions sometimes answers quite well in the case of late Apples. One of the best stores the writer ever saw was a very old lean-to shed facing north-west; it was so low that one had to stoop to enter and inspect the contents. The atmosphere was not really damp, but it always struck one as being so on entering. The Apples were laid several deep on straw placed on shelves and the whole of the remaining space between the shelves was filled with straw, all in a perfectly dry condition. In this case there was no ventilation beyond that afforded by the door, yet

the Apples retained their firmness and soundness till the following April and May. I have seen them do so heaped on a plot of high ground and covered with several cartloads of tree leaves freshly gathered. Quinces should be stored in single layers

like Pears and Medlars, "eye" downwards on layers of clean sand. Nuts keep very well in glass or earthenware jars, the latter being buried under sand in any ordinary cellar or similar cool structure.

GEORGE GARNER.

INSECTIVOROUS PLANTS—III

Cephalotus, Darlingtonia and Sarracenia

UNDER the above heading we come to a consideration of three of the genus of insect-capturing plants which accomplish their work by means of pits or tubes, from which, if the insect can be induced to enter, there is but little chance of a return. Let us take them in the order of the heading, the first of which is *Cephalotus follicularis* or, as it is sometimes called, the New Holland Pitcher Plant. This is, in its duration, a herbaceous perennial, dwarf and compact in habit and with small globular pitchers which are rather variable in their colour, though usually dark green tinged with reddish crimson. Colour is not entirely absent, however, for the lid which stands semi-erect over each pitcher is netted in a very attractive manner with pink veins.

Culturally it is an easy plant to grow, provided its few requirements are understood and supplied. The usual soil, chopped living sphagnum, rough sandy peat and a little charcoal, is suitable as a potting medium. It is extremely important to ensure free drainage and to see that the soil is in a thoroughly porous condition for the roots. During summer, while growth is in an active condition, the plant does best when covered by a bell glass so as to retain a humid atmosphere, but in winter this should be removed as the plants then require drier conditions both at the roots and in the atmosphere.

Propagation may be effected either by a division of the roots or by seeds and the best time to divide is just before new growth pushes up in spring. This, too, is the most suitable time to re-pot, even if division is not contemplated. After potting or division, extra care in watering the plants should be used or they will die; the best plan is one thorough watering immediately after potting is completed, then no more for several days. Always take care, when potting, to mound the pile of compost a little so that the plants are slightly elevated above the rim of the pots, as in this way there is less risk of stagnant water around the crown of the plant.

There is a great difference in the colour of the pitchers according to the degree of light to which they are exposed, but this does not mean that they will appreciate full sunlight. Far from it! They must be shaded from the mid-day sun, though, at the same time, they should receive plenty of light when the sun is not shining directly upon them. Another thing is to avoid excessive heat. The impression that these insect eaters are all tropical plants is entirely false.

The *Dionæa*, *Cephalotus*, *Darlingtonia* and various *Sarracénias* can all be grown in a winter temperature between 45° and 50° and therefore are well within the range of the ordinary greenhouse owner.

The *Darlingtonias* are American and annually produce a rosette of leaves, each one of which is modified into a tall hollow upright pitcher of striking and beautiful appearance and attractive colouring. Each leaf is from 3 ins. to 30 ins. long, according to vigour and variety, and spirally twisted, ending in a hood or crest in the front. Now, observe the device to make the leaf more

flower-like and attractive! The mid rib of the leaf curves over in a rounded form so as to form an orifice and from this hangs a curious little appendage that is coloured in the most vivid crimson and green. Lest the insect should not find this to be sufficient attraction, the exterior of the pitcher bears several honey glands, a free advertisement of the greater joys (?) to be discovered within that delectable-looking tube. Tempted on and on, the insect crawls within and, slipping upon the glossy surface of the tube, falls down. Not right down at first, perhaps, but escape is quite impossible, for there is an array of downward-pointing hairs which makes a return by the way the insect came absolutely impossible. Digestion of the prey is accomplished by means of a liquid excreted from the wall of the pitcher, the result of this digestive process being absorbed through the thin wall of the lower part. Insect capturing is very active in early summer and by midsummer it is not at all uncommon for the pitchers to be filled to a depth of 4 ins. to 6 ins. with decaying remains.

Potting is best done in early July and established plants only need this once in every two or three years. An excellent compost consists of two-thirds of osmunda fibre, with all the dust shaken out, to one-third of sphagnum and plenty of coarse sand. The plants should be covered by a bell glass, for it is most important to maintain a moist atmosphere round them as well as in the soil. Indeed, they are such lovers of a "squishy" soil that it is an excellent plan to cork the drainage hole at the bottom of the pan in which they are grown, then stand this inside another pan slightly larger and pack the space between them with sphagnum that is kept well moist. *Darlingtonia californica* has "pitchers" which are slender at the base and gradually swell outwards until they terminate in a hood bent over at the top. The ground colour of these pitchers is bright green, the upper part and the throat being beautifully mottled with white through which run pink veins. April is the flowering season and the flowers are very large, 4 ins. in diameter. The sepals are white, the petals yellowish-green marked with red veins.

Seeds follow the flowers, but these do not germinate easily. The best method to adopt is to fill a pot to within an inch of the rim with chopped sphagnum moss and fibrous peat in equal proportions, coating the surface with living sphagnum tips. Scatter the seeds on this, cover with a bell glass and place the pots in a shaded position in a cool greenhouse. If the seedlings are going to grow, they will appear in five or six weeks and—when strong enough—they should be pricked off into pans and transferred to shaded cold frames for the summer.

In the Huntsman's Cup or *Sarracenia*, we find a genus that, in addition to its natural species, has been considerably enriched by the labours of the hybridist, resulting in many most interesting and beautiful forms. To gain a general idea of the plants, we cannot do better than describe *Sarracenia purpurea*. This makes leaves 4 ins. to 6 ins. long, blood red in colour and inflated in the middle, contracting again at the mouth; over this pitcher stands an erect kidney-shaped lid that is

plentifully netted with purple veins. This, though by no means reliably hardy, is the hardiest of all the *Sarracénias* and makes a splendid pot plant for the cool or cold greenhouse. Flowers are few in number, purple in colour and borne in early summer on stems 1 ft. high.

If one wants seed from these, note the style at the centre of the flower. This is dilated into a five angled disc, something like an umbrella, with five radiating nerves and it is upon the tips of these that the fertilising pollen must be dusted. Directly the seed is ripe, sow it on the surface of a pan filled with the usual compost and keep cool, shaded and moist. Another way in which further plants can be procured is by careful division of older clumps in early spring, although it is best not to attempt this until fairly large plants have been obtained.

Let us now return again to the pitchers for a few moments and examine these in greater detail in order to discover how they continue to obtain such a giant "bag" of game. That prettily veined lid corresponds to the blade of an ordinary leaf and, in addition to being so beautifully netted and coloured, is furnished on the inner surface with a number of more or less bristling hairs, which once again point downwards, making it fatally easy to descend, but impossible to return. Towards the bottom of the pitcher is a strong rim and this again is barricaded with similar hairs. Tempted further and further by the sugary secretion, the insects find that exit into the happy world of sunlight is unattainable and it is not infrequent to find that the pitchers are nearly filled by the accumulated bodies. Eventually the pitcher dies and falls over, depositing its load of nitrogen just above the roots, ready for them to assimilate.

H. W. CANNING-WRIGHT.

Gardening of the Week

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Beet.—During the next week or two the main-crop may be lifted and stored in a cool shed, where the roots should be covered with ashes or dry sand. In order that the crop may remain in good condition, lift very carefully, avoid breaking the tap root, and screw off the leaves instead of cutting them. If seed was sown in July, the roots can remain in the ground a few more weeks.

Carrots.—Where the roots are large enough they may be lifted and stored in a similar way to the Beet. Late-sown Carrots are growing freely and the young roots are proving useful as a change of vegetable. These are always appreciated, and if a cold frame is available a sowing of a stump-rooted variety may be made with a view to having tender young roots later on.

Radishes.—These may also be sown in cold frames, but a rich soil is not required.

Leeks.—An occasional application of liquid manure or a sprinkling of some fertiliser will benefit this crop. Where Leeks are grown in trenches a little earth should be placed around the base. Keep the space between the lines free from weeds by the use of the hoe at intervals.

General Work.—At this period of the year the garden should be kept as free from weeds as possible, and this can only be done by frequent use of the hoe. If the weather prove wet, all large weeds should be collected and buried in a trench. It is not advisable to take them off the ground, and this remark applies to decaying leaves from Brussels Sprouts and other winter greens which ought to be collected and buried on any vacant piece of land. All vegetable crops should be removed directly they cease to be productive. Tops of Spinach, Pea and Bean haulm and such-like may be placed in a heap to decay, when they may be dug in. Old pea sticks first used this season may be saved for another year, unless they happen to be Birch, when it is policy to burn them. All quarters cleared should be hoed and raked free from weeds; this will prevent any

reaching seeding size. The plot can then remain until an opportunity occurs to dig or trench it.

The Flower Garden.

Delphiniums.—Among plants for the herbaceous borders these occupy a foremost position, and no doubt the best effect is produced by planting them in bold clumps. Although they may be planted at any time during the dormant season, I like to plant either about this date or in early spring. Unless, however, the plants have become unduly large and thereby exhausted the soil, they should be left alone, for frequent disturbance of the roots is not advisable. The ground for Delphiniums should be well prepared by being trenched, a liberal quantity of manure being incorporated at the same time. This is necessary because they should not require lifting again for several years. Strong-growing varieties should be placed 3 ft. apart. Make the soil firm and, if it is dry, give a soaking of water. Slugs are the chief cause of failure, and when growth begins and, in fact, throughout the winter, war must be waged against these marauders. Sharp fine pieces of elms from the stovehole fire if sprinkled around and among the clumps will often hold these pests in check. Seedling Delphiniums require extra care if slugs are not to devour them.

Heucheras.—These form a group of graceful plants for either rock garden or border. Cuttings can now be taken and, if the root-stocks of old plants are exposed they may be top-dressed with a layer of leaf-mould and loam.

Gladioli.—When these have well passed the flowering stage they may be lifted with their growths attached, tied in bundles and then suspended in a shed to dry off. A few weeks later they should be overhauled, the dried growths removed, and the bulbs stored in a dry place until planting-time next year.

The Hardy Fruit Garden.

Grease Bands.—Fruit trees should be banded during the next week or two in order to catch the wingless females of the winter moth. First remove any loose or rough bark from the trunk where it is intended to apply the band of "paraffin" paper, then fix the band by tying it both at the bottom and top with string. Some sticky substance is then smeared on the bands. "Moth Grip," applied with a stiff paint brush, is very reliable, and will remain in a sticky condition for several months. It is, however, necessary to collect the moths from time to time to prevent others from creeping over them. If tree stakes are employed, they will also require a band. Both "Moth Grip" and bands may be purchased from the local nurseryman.

Damsons.—The fruit known as the Langley Bullace is well worth growing. It is the product of a cross between Black Orleans Plum and the Farleigh Damson. It is a valuable addition to the stone fruits, of excellent flavour and a remarkably good cropper. Damson The Merryweather should also be included. The fruit is large and of the true damson flavour. These are both fine fruits for preserving purposes.

Fruits Under Glass.

New Trees.—The planting of fruit trees under glass is not such a task as in the open, but if only one specimen is required, it should be carefully dealt with. Rough specimens with but few fibrous roots should be rejected, for they are rarely satisfactory. The depth at which to plant a tree can be ascertained by an examination of the stem. The soil line can easily be seen, and proves a useful guide to the planter. An important item, especially with Peaches, Nectarines and Cherries, is the cutting back of damaged roots to a sound part. Finish off with a clean cut made with a sharp knife. The roots should be spread out near the surface and the soil worked between, making it moderately firm as the operation proceeds. Give a good watering and do not tie the branches to the wires for a few weeks.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),

Castletord, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Beetroot.—It is too soon yet to lift the tap-rooted Beet, but if the globe or turnip-rooted varieties are fully developed, they should be lifted and placed in the root cellar. In harvesting Beet, care should always be taken, in order to prevent bleeding, not to break the roots. For the same reason the leaves should not be cut,

but should be wrenched off, leaving about 2 ins. of leafstalk attached to the root.

Leeks.—The Leek crop should get a final dressing of some fertiliser of a nitrogenous nature. Those who possess dry fowl or pigeon droppings will find them an efficacious and cheap fertiliser. Pass the droppings through a fine sieve or pound them until fine between two hard substances. Run the Dutch hoe between the crops after applying the fertiliser and a few days later hand-weed the rows if necessary.

Peas.—As the season draws to a close the birds are often very persistent in their attacks upon their favourite vegetable. If stout stakes, higher than the Peas, are driven firmly in at the ends of the rows and a fine wire is stretched taut between them, bunches of feathers or strips of paper can be suspended from the wire, and this will probably scare the marauders away for the short period that the crop has to run.

General Remarks.—All the refuse of harvested crops should be cleared away, and the quarters entirely freed from weeds so that they may be in readiness to be manured, trenched or dug a little later on. The walks, too, should be thoroughly cleaned, after which they should give no further trouble this season.

Edgings.—Box and other edgings requiring replanting may be taken in hand now with advantage, so that the plants may take fresh root before winter sets in. For the kitchen garden Box is undoubtedly the most suitable edging plant and, although relaying it entails a good deal of labour, if trimmed annually it only requires replanting at long periods.

The Hardy Fruit Garden.

Apples.—Most of the early varieties will now be ready for picking. When garnering, care should be taken not to bruise the fruits, as much damage is often done through careless handling. Store the Apples in the fruit-room, which should have been thoroughly cleaned, as previously advised in this column. These early varieties should be used first, as most of them, being rather soft, do not keep well.

Root-Pruning.—Following up the hints on this subject given here a fortnight ago, I now give the *modus operandi*. It is, of course, understood that only one-half of the root area is dealt with the first year. Dig a trench round the area to be operated on, 2 ft. from the trunk of the tree, sever any thick bare roots with a mattock. Excavate right under the tree, cutting all thick roots. Having done this, proceed to trim the cuts clean with a sharp knife. If some maiden loam is available, fill up the entire excavated space with it. Failing this, use the top spit of good garden soil with some old mortar rubble intermixed. Pack the soil firmly as it is being filled in and the operation is complete. If several trees are to be dealt with, prune them all on the same side, east or west as the case may be, and make a note of the fact, as memory is not always to be trusted.

The Rock Garden.

Propagation.—A good many plants may now be propagated by cuttings and rooted in a cold frame. Among soft-wooded plants the following may be dealt with: *Viola cornuta* and *V. gracilis*, including the white variety; varieties of *Phlox frondosa*, *Aubrietias*, *Dianthus*, *Alyssums*, *Campanulas* and *Cheiranthuses*. Among hard-wooded plants for similar treatment are *Hypericums*, *Muehlenbeckias*, *Veronicas*, *Rhododendrons* (dwarf and prostrate species), *Daphnes* and *Skimmia japonica*.

General Remarks.—A general clean-up should now be given. This will include the cutting away of all spent flowers and decayed stems, the removal of decayed leaves and the uprooting of all weeds. Any pockets that show signs of sourness should have some of the surface soil removed and replaced by a fresh compost of a more porous nature. Other pockets shewing a baked surface will be benefited by being pricked over with the handfork.

The Flower Garden.

Carnations.—Those who have to deal with heavy retentive soils and therefore find it expedient to practise spring planting should lift the layers and pot them up into 3 in. pots. Place them in a cold frame on a layer of coal ashes, but do not put on the sashes for a few weeks. When these are put on, an abundance of air must be admitted at all times, as any tendency to coddling will weaken the plants. Keep a sharp look-out for mice, as they are very fond of Carnations.

Montbretias.—The general advice with regard to these beautiful autumn flowers is to lift the

corms as soon as the foliage has ripened and to dry them off under cover, planting them out again in spring. I have not tested the hardness of some of the finer varieties, but I have left such varieties as *Etoile de Feu*, *Pottsi*, *Rayon d'Or* and *Vulcan* in position for a second year with good results, and any of the varieties will come safely through the winter if they are lifted and "sheathed in" in a sheltered spot and protected by a few leaves or any kind of dry litter. Treated thus there is less danger of any of the corms dying than when they are lifted and dried off.

Schizostylis coccinea, familiarly known as the Kafir Lily, is an attractive little bulbous plant, its bright red flowers being very welcome during the dull days of autumn, when outdoor flowers have become scarce. It is all but absolutely hardy, though a native of the Cape. It is certainly quite hardy when planted in rather light soil in a sheltered position. It increases rapidly, and should be lifted and divided every second or third year.

Lilium candidum.—The Madonna Lily is probably the most popular member of the whole genus, its fragrant flowers of purest white, freely produced, appealing to every lover of flowers. It is easy of culture, but there is one condition which must be observed. It is essential to replant (or purchase and plant) the bulbs immediately after the foliage has died down, for delay may probably mean disaster.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian.)

GREENHOUSE AND CONSERVATORY.

Sweet Peas.—Where it is desired to grow Sweet Peas in pots, the seed should be sown towards the end of the month or during October. Early sowing is not desirable, as it is no advantage to have them too forward for the winter. Where only small quantities are required, it is best to sow about five seeds in each 48-sized pot. The young plants can remain in these pots through the dark days and be potted on early in the New Year. Where large quantities are required, the seeds may be sown in pans or boxes and the plantlets be afterwards transferred to pots. Before sowing, the seeds should be dressed with red lead to prevent mice attacking them. Where this is not done the seed pots or pans should be covered with pieces of glass until germination takes place. The seed pots should be stood in cold frames, and after germination the young plants should be given plenty of air. Remove the lights entirely on every favourable occasion, as it is essential that the plants be kept strong and sturdy. A sharp look-out should be kept for slugs. Sparrows, too, are very fond of them and often prove troublesome, and it may be necessary to protect them in some way.

Bulbs for Forcing.—As they come to hand all bulbs intended for forcing should, as already advised, be potted up without delay. Darwin Tulips are very useful for this purpose, their long stems rendering them specially valuable where a supply of cut flowers is required. They are, however, by no means so easily managed as the early-flowering varieties, as they will not stand the same amount of forcing. I feel sure that when they are intended for conservatory decoration failures are often due to growing them in too small pots. I find, indeed, that the best results are obtained by growing five or six bulbs in each 5 in. pot.

Campanula pyramidalis.—Plants raised from seed sown early in the year should now be ready for potting into 7 in. pots. They are best wintered in cold frames, leaving the lights off on every possible occasion. If frames are not available, the plants can be safely wintered at the foot of a wall, plunging the pots to the rims in ashes. In the South at least they are hardy, and fine plants can be obtained by growing them outdoors and lifting them at this time from the open ground, or they may be left until next spring before they are lifted and potted up.

Asclepias curassavica.—This plant is very useful for conservatory decoration, and is usually sown during the spring for flowering during the summer months. It is so useful a plant that it is a good plan to sow some seed at this time for flowering next spring and early summer. It succeeds quite well in an ordinary greenhouse. As this *Asclepias* is of slender growth, the best results are obtained by putting four or five plants in a 6 in. pot. Although generally treated as an annual, it may be grown on for a second year, when the plants will send up a number of shoots from the base.

Chrysanthemum frutescens var. Mrs. F. Sander. This fine double-flowered variety is very useful for decorative work. For flowering early next summer, plants should be rooted at this time. Good cuttings are often difficult to obtain, but may usually be provided by partly cutting back a few plants and placing them in a fairly close house a few weeks before the cuttings are required.

Brodiaeas are seldom seen in gardens at the present day, and although fairly hardy in warm situations, they are worthy of more general attention for pot culture. They are especially useful for the unheated greenhouse. Their successful cultivation presents no difficulty, as they grow quite well in any ordinary potting compost, planting five or six bulbs together in a 6-in. pot. There are several species that can be used for this purpose, notably *B. capitata*, *coccinea*, *grandiflora*, *Howellii*, *ixioides*, *multiflora* and *vulgaris*.

Origanum hybridum. This plant, although hardy outdoors in the South, is very pretty and useful for greenhouse decoration in September, during which month it is always difficult to get an interesting variety of plants for the conservatory. If cuttings are inserted at this time, they will make good plants for next year. Good examples can be grown in 48-sized pots, in which size they are very useful for decorative work. The light elegant sprays are also very useful for cutting. It grows freely in any ordinary potting compost and requires perfectly cool treatment at all stages of its cultivation. When in flower it should be freely exposed to sun and air, as the rosy red colour of the bracts is then intensified.

Azaleas of the indicum section, although they will stand a few degrees of frost without injury, should now be got indoors. They are best in a perfectly cool house, where they can be kept quiescent until such time as they are required for forcing. For early forcing the earliest-flowering varieties should be selected. Having been used for this purpose last season, their growth, naturally, was completed early, and they are thus in good condition for early forcing. After they have been brought indoors the house should be kept fairly moist for a time, otherwise in the drier atmosphere they are apt to lose a lot of their foliage.

Zonal Pelargoniums grown for winter flowering should now be allowed to develop their flowers in successional batches according to requirements. They enjoy a warm, dry atmosphere with a little fire-heat during dull weather. During such dull spells watering should be very carefully done, as they are very impatient of excessive moisture. In the immediate neighbourhood of London they are very uncertain during the winter. One night's fog is sufficient to spoil them. Under such circumstances it is best to get them in flower during October and early November, before there is much danger of fogs.

Royal Botanic Gardens, Kew.

J. COUTTS.

A Pretty Bindweed.—The slender-growing *Convolvulus althaeoides*, with silvery leaves and large, rose-coloured flowers, is little known and, consequently, seldom found in gardens. It shares to some degree the roaming propensities of its allies, but is not quite so much given to spreading in the outrageous fashion some of the other *Convolvuli* affect. It is not a tall grower and the best place for it is by the side of a slender shrub over which it can grow without doing it any material injury. It is hardy and likes a sunny place in light soil, where it will thrive and give its pretty flowers annually in summer.

A Fine Form of Aster alpinus. Only those of us who knew *Aster alpinus* when our choice was confined to the four older forms, *A. alpinus* itself, *A. a. albus*, the white variety, and *A. a. roseus*, and then the bigger one, *A. a. superbus*, can fully appreciate the larger varieties. We have watched this advance with interest and it is pleasant to see that contemporaneously with this progress a new interest has been taken in the flower by lovers of rock gardens. Several notable examples of the new varieties have been seen in London of late years, and at the last Chelsea Show some magnificent forms were exhibited. Among these we noted the Wargrave variety, shown by Messrs. Waterer, Sons and Crisp, a variety of high excellence some 6 ins. high with (for an *A. alpinus*) immense flowers of a fine purple blue. It deserves the consideration

of those about to add varieties of *A. alpinus* to their gardens.

Michaelmas Daisy Snowball. Good white Michaelmas Daisies are always appreciated and there is likely to be a demand for that named Snowball, sent out a year or two ago, when it becomes better known. For the small garden its moderate height—2 ft.—is a recommendation, while its double flowers appeal to a good many, although some have not yet overcome their objections to the doubling of the blooms of the Starworts. Yet these double flowers seem to stand the weather well and to last a good while in bloom. In Snowball they are of good doubleness, and open pure white. The only drawback—and this is common to practically the whole of the white Michaelmas Daisies—is that they pass off pink with age. However, we cannot have everything we wish and Aster Snowball is really a variety worth growing in the garden.

The Common Barberry.—Notwithstanding the many novelties of great merit which have been introduced within recent times the Common Barberry (*Berberis vulgaris*) can still claim a place among the best. This familiar native shrub, often to be seen in hedgerows and waste places in some localities, is a deciduous species with very spiny branches, soft green leaves and a stature up to 10 ft. It is very charming in spring, when its comparatively large and conspicuous racemes of yellow hang from the elegant branches, but its most notable feature is the crop of scarlet fruits which it bears so generously, usually with unfailing regularity every year. These fruits are almost cylindrical, sometimes egg-shaped, and begin to colour in August or earlier. Yet they do not reach their fullest splendour until touched by the first frosts of autumn, when they assume a brilliance not excelled, perhaps not equalled, by those of any other member of the genus. Moreover, being very acid, these fruits are disliked by birds, so that they may often be seen on the branches through the greater part of the winter. Their tartness, however, is by no means unpleasant and they are still used in country places as a substitute for capers, as a candied fruit and as a commendable addition to the jar of home-made pickles and chutneys. *B. vulgaris* is one of the most accommodating of shrubs, doing well almost anywhere, without complaint. It makes a handsome specimen bush, an impenetrable and highly attractive hedge and is useful for grouping in rough, stony corners where most shrubs of equal merit would fail to succeed. There are many varieties, chiefly differing in the colours of their fruits and leaves. The best of these is probably *purpurea*, a form which is precisely like the type in all but the foliage which is a warm plum purple tending to crimson on the young wood. Though a handsome shrub, this variety is hardly so attractive when in fruit as the type.

Trial of Delphiniums at Wisley. The Royal Horticultural Society will carry out during the coming season a trial of Delphiniums in their gardens at Wisley. Three plants of each variety should be sent so as to reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey (goods to Horsley Station, Southern Railway) on or before October 30. The necessary entry forms may be obtained on application to him.

FORTHCOMING EVENTS.

September 26. Mitcham, Tooting and District Horticultural Society's Meeting.

September 27. Royal Botanic Society's Meeting, Wargrave and District Gardeners' Society's Meeting.

September 29. Finchley Chrysanthemum Society's Exhibition.

ANSWERS TO CORRESPONDENTS

ROSE GARDEN.

PREPARING FOR ROSES ("Roses," Wores).—Certainly from what our correspondent states, cow dung would be preferable to horse droppings as a fertiliser. A early liberal sprinkling of both such bones would also be helpful, and it would be of immense benefit if some really good turfy loam could be introduced. Deep cultivation is, of course, essential.

FRUITS UNDER GLASS.

POT VINES WITH FLATTENED CANES (O. W.).—Several causes conduce to the growth of flat canes, namely: potting in a too rich, retentive soil and not ramming the soil sufficiently firmly; a too damp atmosphere and lack of ventilation during the growing stages. Firm potting in fibrous, porous soil, ample ventilation and full exposure to light (an essential consolidating agent), mean short-jointed, round-stemmed Vines.

VINES AND PEACHES UNSATISFACTORY (J. M.).—Over dryness of the soil, or a very wet, stagnant condition would cause mildew to appear on the vine leaves and bunches. Undoubtedly the roots were too dry during the early part of the summer. Improper regulation of the ventilation is another cause. The winds were very cold throughout the spring and early summer time and undue exposure of the tender leaves to cold draughts would favour the rapid spread of mildew. The bunches of Grapes are quite useless; cut and burn them, then thoroughly syringe the vines with "Abol," carefully following the instructions. When the Vines are duly pruned, burn the prunings and paint the rods—all except the young bud—with a paste of flowers of sulphur. The work done to the roots by the gardener would not cause the mildew. The soil around the roots of the Peach trees was also too dry; it should not be allowed to become dry throughout the year; a bad attack of red spider would hasten the falling of the leaves.

FRUIT GARDEN.

PEAR FOLIAGE BLIGHTED (D. H. S.-S.).—The foliage of the Pear tree has been attacked by the larvae of the pear sawfly, *Eriocampa liliaceana*. The pest passes the winter in the top 3 ins. of soil. Early in June the winged insects appear and lay eggs in the leaves. From these eggs come the small green "slugs" which do the damage. During the winter the top ins. of soil around the tree should be removed and burned in order to destroy the hibernating larva. Early in June a watch should be kept for the "slugs," and if any appear they should be poisoned by spraying with "Katakilla."

PLUMS FOR PLANTING ON A NORTH WALL (Felsed).—Yes, our correspondent may safely plant the varieties of Plums on a north wall. The variety River's Early Prolific flowers early and would be more likely to escape late frosts in a north aspect.

KITCHEN GARDEN.

CUCUMBER FAILING (J. R., North Wales).—The Cucumbers are troubled with what is often known as "canker." The stem decays at the junction with the root. This is encouraged by sour soil and we suspect this is the existing cause of the trouble. The roots have not developed well at any time apparently and we recommend that the whole of the soil should be removed and replaced with fresh of a less sour nature.

MISCELLANEOUS.

VARIOUS QUESTIONS (G. G., Bas-sacks).—Our correspondent will do right to cut out the decayed limb to sound wood in the case of the Mulberry tree and dress it as suggested. First, however, wash the wound with a strong salt solution. Reput the Stocks and Canterbury Bells at once, using 6-in. pots. To prevent damping off of the latter simply water and ventilate with ordinary care, especially in foggy weather. We have asked Mr. George Garner, who first discovered the soot treatment, for silver-leaf, to let us have notes on the treatment to date. He replies as follows: "Your correspondent must begin the treatment at the end of September. Procure some fresh soot, mix with water till it is of the consistency of mortar, then spread out the mixture thickly on the surface and over a wide enough space to cover the roots of the tree. Generally, I find an ordinary bucketful sufficient for one dressing. At least three—better five—applications should be given from October to March at stated intervals. Once each week the soot should be washed in thoroughly, using clear water applied through a rosed watering-can. Repeat a second winter, and in summer syringe the foliage occasionally with clear soot-water while the green fruits are swelling. Badly affected branches should be cut out now and burned, the wounds being dressed with painters' "knotting" or styptic. Orchard Plums and other trees, inside and out, should be treated similarly."

BARR'S Beautiful New Seedling NERINES

The most beautiful and easiest grown of Autumn-flowering Bulbs for the Greenhouse.

For autumn decoration in the greenhouse few plants can compare with Nerines for their brilliant and attractive colours. The flowers, produced in umbels of 6 to 24 blooms, are borne on stout stems from 1 to 2 feet high. The colours range from dark red, vivid crimson, cerise and scarlet to salmon, coral-rose, pink, blush and white, many having a glistening lustre which in sunlight gives them the appearance of being dusted with gold or silver. They remain decorative for many weeks, and their beauty may be enjoyed in a sitting-room as well as the greenhouse, if the pots are kept in a sunny window.

12 in 12 beautiful named varieties .. 42/-, 50/-, 63/- and 84/-
6 in 6 .. 18/-, 24/-, 30/- and 42/-
Mixed Hybrid Nerines (un-named) .. per doz. 25/-; each 2/6

SPECIAL LIST ON APPLICATION.

ALFRED EDWARDS, F.R.H.S., Fordham, ELY.

DOBBIE'S SCOTCH-GROWN ROSES

are **NOT** propagated cheaply on the unsatisfactory Manetti Stock, nor are they budded on the ordinary Dog Briar so liable to the scourge of mildew, but on a Stock proved over many years to be the best. It is earlier and hardier than the Briar and, in itself, absolutely free from mildew. Growers should get the best even if prices for quality are slightly higher.

CATALOGUE ON APPLICATION.

Notes from Maidstone.

BUYING A HORSE.

*It would be very difficult
to buy a horse from a
catalogue. One might
be cheap at £500 and
another dear at £5.
In a less degree the same
applies to plants, price
and value not being
synonyms. A personal
comparison not being
always possible, therefore
one falls back on the
reputation of the seller,
and if an English firm
one has a certain satis-
faction in knowing one's
malisons, if necessary,
will not be read as
benisons.*

The NATIONAL FLOWER

No. 2706.—VOL. LXXXVII.]

[SEPTEMBER 29, 1923.]

SOME ORNAMENTAL CHERRIES

THE Cherry is a lime-loving tree and most species do best on marly soils, yet no soil, except, perhaps, a cold, heavy clay, is unfitted for their culture and one of our native species, the Gean, *Prunus Avium*, may be seen flourishing in woodland in practically all parts of the country. Even the hungry Sussex forests grow fine specimens. The double-flowered form of this tree is very beautiful and worthy of a place in all gardens of any size. A Cherry orchard when in flower is a wonderful sight and many people who have small expectation of gathering any considerable crop, owing to feathered depredators, grow standard trees of the fruiting Cherries almost entirely for their decorative value.

This notwithstanding, almost all the Cherries which are really beautiful when in flower are of Oriental origin, and as the planting season is now upon us, it may seem fitting to describe some of the best. This is the more necessary owing to the confusion which exists as to nomenclature. No doubt the botanists have good reasons for collecting together into one great genus all the Almonds, Peaches, Cherries, Plums, Apricots, Bird Cherries and Cherry Laurels, but this kind of classification is the reverse of helpful to the gardener. It is with the true Cherries that we are concerned in these notes.

The principal types of the Japanese Cherries are *Prunus serrulata* and PP. *Launesiana* and *subhirtella*. The best single form of *P. serrulata* is var. *sachalinensis*, of which some splendid trees exist in Japan, but *P. serrulata* as grown in our gardens is double, there being pure white and pretty rose forms. There are several double forms of *P. s. sachalinensis*, one fairly often met with in English gardens being *Shirofugen*, also known as *albo-rosea*, which latter name is satisfactorily colour-descriptive. Other good forms on the authority of that great traveller, Mr. E. H. Wilson, now of the Arnold Arboretum, are *Kirin*, *Horinji*, *Ichiyo*, *Fugenzo* and the late-flowering *Sekiyama* or *Kanzan*. Which of these, if any, are procurable at the present time in Britain it would be difficult to say, but *Fugenzo* is variously listed

here as *Benifugen*, *Veitchiana* and *James H. Veitch*. *P. serrulata spontanea*, with single white flowers and foliage glaucous beneath, is now listed and is a very beautiful free-growing Cherry. Apparently the double *Hisakura* or *New Red* is a form of *P. serrulata sachalinensis*. This has double flowers of so deep a rose as almost to merit its English name and foliage which at blossoming time is a lovely deep bronze. This is one of the most vigorous-growing of double Oriental Cherries and should be in every collection. *P. Launesiana* var. *albida*, says Wilson, is "not so hardy as the

varieties of *serrulata*, nor so long lived, though of rapid growth." In this country it is usually sold as *P. japonica alba simplex*. Some of the best varieties of this plant are apparently not in cultivation here, but *Ojochin* is procurable with large double white flowers, so are *Amanogawa*, also known as *Apple Blossom*, which is a very upright grower with blush pink blossoms and late to flower; *Senriko* (*Mount Fuji*), said to be the finest of the semi-double whites; and *Ukon* or *Asagi*, with pale greenish-yellow flowers. *Ukon*, as grown in this country, seems to have fewer petals than the semi-double form listed as *lutea flore pleno*, which is otherwise identical with it.

P. Sieboldii, with pubescent twigs and foliage, is usually represented in gardens by the tree known as *Watereri*, which has large semi-double clear rose coloured flowers. This, again, is generally regarded as synonymous with *Naden*, but, as we have seen the latter growing in some collections, it is almost single and rather paler in hue, though obviously a form of the same species. Both are good plants.

The Rosebud Cherries are very distinct in appearance and according to our classification belong to three species, PP. *subhirtella*, *pendula* and *microlepis*, but Wilson considers them all to be forms of one species. They are, at any rate, sufficiently distinct to reproduce themselves true from seed. *P. subhirtella*, as grown in this country, forms a small tree which is exceedingly floriferous. What is no doubt the typical species is known as var. *ascendens*, which attains the dimensions of a forest tree and is now, perhaps, procurable in this country.

P. pendula (*P. sinensis pendula rosea* of some catalogues and *P. subhirtella pendula* of others), is, as we know it in this country, a particularly graceful weeping tree, which has frequently been illustrated in *THE GARDEN*. When smothered with rosy buds and just expanding blossoms, it is a sight worth going far to see, yet does it not compare with fine old specimens of the same species as seen in Japan. We have in gardens a tree known as variety *carnea* of this. Similar in most respects, it differs notably in that the flowers are borne on longer stalked corymbs and in the presence of several bracts where

ONE OF THE BEST FORMS OF PRUNUS LANNESIANA, UKON, WITH GREENISH YELLOW BLOSSOMS.

the midrib of the flower-stalk join the stalk, carrying the corolla. The third species of Rosebud Cherry is *P. amoenum* of Koehne, which Wilson prefers to *P. subhirtella* var. *autumnalis* and which in England is often grown and known as *P. Miqueliana*. *P. Miqueliana* of Maximowicz it is not. This tree was introduced to British gardens by the firm of T. Smith of Newry about 1911. It has semi-double flowers and is remarkable for coming into flower in late autumn, usually in November.

The Rosebud Cherries form together a very interesting species or group of species, whichever way one regards them. They are very distinct from the other Japanese species such as *serrulata*, *Pseudo-cerasus*, *Lannesiana* or *Sieboldii*. Their slender, whip-like growths and rather small pinkish flowers, always bright rose in the bud stage, make them easily recognisable. There is no difficulty in raising them from seeds, and any seedlings which proved inferior as regards colouring or floriferousness might well be utilised as stocks for the better forms.

Quick growing and handsome is the Tokio Cherry, *P. yedoensis* (also listed as *Yoshino Zakurai*), with white or blush-coloured flowers. This might well be utilised anywhere where a large tree would be desirable and might replace the double Gean on occasion.

P. Maximowiczii is perhaps more interesting than beautiful. The small flowers are dull greenish white and produced six or ten together. The racemes are more notable, however, for the large leafy bracts than for the flowers themselves.

P. nersa, the Pigmy Cherry of Japan, is now procurable in this country. It is a small grower in stature about the size of *Cotoneaster frigida* as a rule, but quite one of the most attractive species. The blossoms are white or pale rose and the stamens are red, which adds a great deal of life to the flowers. The sepals also are ruddy.

P. Pseudo-cerasus is often taken as typical of the Japanese Cherries, being confused with *P. serrulata*. *P. Pseudo-cerasus* is much less effective and less hardy and is very seldom seen in this country outside Botanic Gardens. It is doubtful if it is at present in commerce.

This about concludes the list of Asiatic species at present in commerce in Britain, but there are several European species and varieties which are worth a place in every extensive garden. Some are as beautiful as the Oriental kinds.

The All Saints' Cherry, *P. alba semperflorans*, is a remarkable variety which bears white flowers on the leafless branches in April, but not very freely. It flowers again, remarkably enough, from the young wood, in June and continues to do so

until September, so that very often there are flowers and fruits on the tree at the same time. This may be grown as a large bush or, grafted on the head, as a small round-headed lawn tree. The fruits are acid, but quite edible.

The St. Lucie Cherry, *Cerasus Mahaleb*, again, is a very beautiful tree and particularly suitable for sandy soils, upon which it grows more thriftily and flowers more freely than upon fertile loams. Like all the European Cherries the blossoms are white. The best form of the tree for pleasure-ground planting is called *pendula*. Not strikingly pendulous this is sufficiently so to give it added grace.

The Double Morello, *P. Cerasus flore pleno*, also known as *Rhexi* and *ramunculiflora*, is quite the best small-growing double white Cherry we have. The flowers are good white, rûms. across and very double. It is a more compact grower than *P. Avium flore pleno*.

It is nowadays easier to obtain the Oriental Cherries grafted on suitable stocks than was the case until recently. It is very true that Japanese Cherries, forms of *serrulata* or *Lannesiana*, may be seen twenty or thirty years old and still living and flowering on *Avium* or *Cerasus* stocks. It stands to reason, however, that species so alien to the stocks cannot be expected to thrive as they would if budded or grafted on stocks of their own species.

A SPLENDID TREE OF THE WEEPING ROSEBUD CHERRY, *CERASUS PENDULA*, IN JAPAN.

By permission of the Arnold Arboretum.

AUTUMN AND ITS FLOWERS

SEPTEMBER rains and genial sun do much for the pastures and hedgerows, bringing a more lively green to the one and a few fresh Dog Roses and Honeysuckle clusters to the other. In the same way they induce many things of the garden to break into that second flowering which is always so delightful. Yet, though I say "always," it is not that I am unconscious of the fact that autumn blooms to some plants may mean a heavy mortgage on the latter's spring production. It is distressing, perhaps, to find certain Rhododendrons shewing colour now instead of in May. This notwithstanding, his is a cold heart which cannot share the common revival, transitory and beset with dangers as it may be, which this season brings, and rejoice that there is a youth that is still young enough in this old world to "swim on bladders" and take the consequences.

As a matter of fact, and omitting entirely the Roses, the appreciation and enthusiasm which are inspired by these autumn blooms are not to be accounted for solely because they, the latter, are comparatively few and therefore the more warmly greeted individually, but because they are so often finer and of a better colour than those of the earlier flowering were. A notable instance is afforded by the good old *Geranium grandiflorum*, of which the flowers to-day are larger and of a purer colour than those of the first blossoming. So much may also be said of *GG. Endressi* and *striatum*, of the dainty *cinereum* and *argenteum* and that splendid offshoot of *Traversii*, "*Russell Prichard*," which last, even now, shews few signs of failing vigour.

Then there is the wonderful blue of *Omphalodes cappadocica*, sprays of purest azure which gleam with a light even more intensely clear than that of its April blossoms, which is saying much, as those who know this lovely thing will admit. *O. cappadocica* is, with us, one of those plants of which the second flowering is no mere accident dependent upon the caprice of the weather. It comes with the Mushrooms and no less regularly, and outlives them, totally quenching the "ineffectual fires" of *Cynoglossum appeninum* and putting to shame sisters *nitida* and *verna*, which make no response to the sweet influences of September. Though one recognises the fact that the sun has lost the bleaching effect that it had on many blossoms, it is doubtless true that there is a quality in the light at this season which gives blue flowers, or any of those approaching that tint, a notable refinement of tone. It may even endow them with properties they do not actually possess. That adorable little *Viola*, *Lady Crisp*, such a reliable and prolific autumn bloomer, may have been described as a cool lavender two months ago; to-day it is very nearly blue, and the old *V. cornuta*, of which as much might have been said of its earlier flowers, is still bluer. The same subtle alchemist responsible for this also so transforms the blossoms of the Greater Periwinkle that one suddenly realises that there is such a colour as "periwinkle blue" after all. *Aster acris* could hardly at any other season make the same appeal that it does to-day, when the red is filtered from its shaggy rays, causing the blue to predominate

with such extraordinary intensity. Again, I should not like to say that the flowers of *Aster pyrenaicus*, or any other late bloomer of its peculiar tint, would approach so nearly the hue of *Agathaea celestis* at any other season but this. As for the lesser *Campanulas* one might mention a dozen whose few autumn blooms differ so greatly in tone from those of the same plants at midsummer that they might be taken to be distinct forms.

Among others which are making a generous response to these kindly September days is the prostrate *Rosemary*, which has burnished-up its lusty green and produced a fine crop of flowers. The shrubby *Potentillas*, again, notably *PP. Vilmoriniana* and *Farreri*, are blooming as heartily as they were in haytime, and so is *P. arbuscula*, with larger flowers than either of the above, and these in a golden yellow of the richest dye. A dwarfier and very charming member of the same household is *P. fruticosa nana argentea*, but whether it has any right to that name I shall not attempt to decide.

ONE OF EARLY AUTUMN'S MOST EFFECTIVE PLANTS, *ASTER ACRIS*.

Cistuses are not as a rule good "back-end" bloomers, but *C. corbariensis* is an exception, being practically perpetual here. *C. Hillierii* has been in flower all the month and looks like continuing for some time. There are buds breaking on *C. purpureus* as I write and these will doubtless produce flowers not less generous in size and colour than were the first to open. Another *Cistus* that cannot resist indulging in late blooms is the rosy-carmine variety "*Sunset*" of *C. crispus*. *CC. (Helianthemum) formosum* and *unicolor* are bright with their lovely yellow flowers every sunny morning, *alyssoides* has put up a fresh crop of colour and, if *H. umbellatum* is rather more shy at this season, the few milk-white cups which come to adorn its dark-green, yew-like foliage are too precious to be missed. The best of the yellow *Linums* for late-flowering here is *L. capitatum* and its citron yellow makes a bright patch of colour on the top of a retaining wall. This is

always a more certain autumn bloomer than *L. arboreum*, but *L. flavum*, under similar conditions, would probably be as good.

Always one of the most cheerful plants in the rock garden throughout this season is *Mesembryanthemum uncinatum*. This is quite hardy here, being probably the hardiest of its kind, and it makes a neat, branching shrublet about roins high which it covers with a galaxy of bright little crimson and white stars. We have never known this species to be injured by frost. Others among these sun-worshippers which are tolerably hardy, often living for years unprotected in the gritty soil of a rock garden ledge, are the very attractive *Brownii*, *crassulaceum*, *luteum*, *turbinatum* and the glowing violet *violaceum*.

Having been held back by drought the shell-pink, waxen trumpets of *Putoria calabrica*, which grow in clusters like those of *Daphne Cneorum* at the ends of their little branches, have come to join these autumnal efforts, but they are none the less welcome for being late. This tiny bushling from the sunny cliffs of Southern Europe appears to need a warm, dry crevice, yet not too dry lest

its blooming, as I have suggested, may be thrown far into autumn. Like a good many other things it probably enjoys summer moisture, but needs to be shielded from excessive wet at other seasons.

P. calabrica, however, is not the only plant of which the flowering date is decided by the whims of the weather. In days like ours when every urchin knows all about gardening from his collection of cigarette cards, I suppose one ought to be able to overcome such irregularities as plants commit, and insist on punctuality, implicit obedience and the rest. But there it is. *P. calabrica* lies in a dog's sleep all summer. *Polygonum sino-capitatum* pleases itself whether it blooms in July or the end of September, and *P. vacinifolium* will this year not be in full flower until towards the end of September. This last, perhaps the most beautiful of its race, may plead that it never pretended to be anything else but an autumn-flowerer. Even so, some glorious masses grown in full sun in

wet soil and toppling over the rocky margin of a pond, were last year among the most beautiful objects of a neighbour's garden as early as July.

Origanum Dictamnus, the Cretan Marjoram, is much more faithful to its appointed hour, seldom displaying its hop-like flower clusters until the days grow perceptibly shorter. This is not a plant that can lay claim to much merit, but it is one which has a quiet, unobtrusive way of winning one's affections. After all, there is something very attractive about those nodding, lumpy flower heads, ticked with rosy-lilac, and the silky leaves where grey-green is suffused with the same stain of ruby-crimson that adorns the flower bracts. Then I suppose the fact that *O. Dictamnus* is by no means really hardy makes a certain appeal to one's sympathies. *Origanum pulchrum*, having smoother foliage, is probably more robust than the Cretan plant, but in other respects, if my identification fails not, it is much like the latter. A good word must be put in here for *Oxalis*

floribunda alba, which has maintained such a worthy succession of blossoms all summer and which promises a continuance until the very end of autumn. Certainly, to be just, *O. lutea* is equally productive, but in a garden where the latter grows with the profusion of a ramping weed, one is apt to under-estimate its good qualities. The best really late-flowering species of this tribe in bloom here at the time of writing is *O. Depperi*. The handsome trefoil leaves of this Wood Sorrel, often 2 ins. across, are a beautiful apple-green, with crescentic markings in maroon, and the flowers, borne in clusters at the head of 8 in. stems, are a warm red—just the colour for an autumn garden. Is this, by the way, the same *O. Depperi* which, according to an old gardening book by me, is a Mexican species introduced in 1827? The same book goes on to explain at considerable length the culture of *O. Depperi* as a vegetable and gives various methods of cooking and serving the bulbs as well as the leaves, the latter in salads! NORTH WALES.

THE CULTURE OF THE PERSIAN CYCLAMEN

THE beautiful Cyclamen is especially a plant for everyone and, happily, those giant, well-leaved plants, furnished with dozens of flowers and buds, are not difficult of attainment. One point, and one only, must be kept in the forefront of the mind, right from the day when the seed is sown to the time when they are grouped in the greenhouse or conservatory, *i.e.*, steady and continuous growth. A non-stop run from the seed pan to the flowering stage can scarcely result in failure; it is from those checked plants in which the swelling corns become skin-bound that stunted leafage and sparse flowering almost inevitably result. With so important a flower, it is scarcely necessary to insist upon the importance of a good strain of seed, whether this be named or mixed.

Now to the practical work of sowing and raising the plants. Make up a compost of equal parts of good fibrous loam, thoroughly rotted hot-bed

manure and silver sand, taking care that this is thoroughly mixed and then put it into well drained pans or boxes, to a depth of about 3 ins., making the surface smooth and level.

Upon opening the packet one finds (especially if the varieties are mixed), that the seeds vary considerably in size. The best way to distribute them is by going over the surface of the pan and dibbling small holes with the end of a match at distances of 1 in. apart and ½ in. deep. Into each of these holes drop a single seed and make the holes slightly shallower for the smaller seeds, so that they are not buried too deeply. Press down the surface of the soil gently, water through a fine rosed can and cover each box with a pane of glass. These pans should be stood in a house where the minimum temperature does not fall below 55°. Here they will require but little watering, for it is only necessary to keep the soil just moist until the wee plantlets appear. The glass should

then be withdrawn and the pans placed in a good light near the glass, so as to prevent the little plants becoming drawn and to keep the growth sturdy. By sowing at the above distance, it will not be necessary to transplant until early February, by which time they will have advanced sufficiently for transfer to small pots. Through the winter a steady temperature of 50° to 60° suits them admirably and care should be taken never to allow the atmosphere to become dry, a very vital point in successful cultivation. If one wants to save labour, it is a good plan to lift the plants from the boxes or pans in which they were sown and transfer to further boxes, 3 ins. apart each way, as it is far simpler to attend to their wants in the direction of watering and so forth where a quantity of plants are contained in a box than when the same quantity are distributed over an equal number of pots.

Do not overlook the fact that we often get spells of bright sunshine in early spring and that newly boxed plants need shading until the roots are working freely again. Even then, although Cyclamens enjoy abundant light, direct sunshine should be screened. About the time the plantlets make their fifth leaf is an excellent period to choose for placing in the first pots, for simultaneously with this they begin to push out strong feeding roots from the base of the corns. Perfectly clean, well drained 4 in. pots are a suitable size to use. Make up a heap of similar soil and run this through a coarse sieve so as to divide it into two heaps, the finer for the actual potting, the coarser to be used for putting over the drainage holes and crocks. Half fill the pots with compost, then lift a seedling from the box with as much soil as possible adhering to the roots, drop it into the pot and fill in round the edge with further soil. One should be careful to press this down very lightly with the fingers for the Cyclamen loves a loose soil through which the roots can run very easily, and anything like hard potting brings the growth to an immediate standstill. Unlike most corns or tubers the Cyclamen should not be buried beneath the earth, but "sit" upon the top of it with the soil sloping away on all sides to the rim of the pot. When, therefore, one lifts the plants from the seed boxes, plant them in the pots at such a level that about one-third of the depth of the corn is below the surface and the other two-thirds above it.

Place the pots in a warmer temperature for a short time, shade from sunlight, use tepid water for moistening the soil and damp overhead twice a day and the plants will continue growing without the slightest pause. As the natural temperature increases, more and more air may be admitted, but care should be taken that this is not allowed to become dry or pests will begin to prove troublesome. After the lapse of about eight weeks, the plants will be fit for a further shift into 6 in. flowering pots. By this time they should have built up good sized healthy corns, well furnished with leaves and roots and therefore in a condition to absorb stronger food. Use a similar compost, but reduce the amount of sand and do not sift the soil. Equal care should be taken not to make the soil too firm and they should be returned to the same position and identical cultural conditions carried on, except that they should be kept a little closer for a few days. Through August, which is usually the most trying period of their lives, because of the heat, every possible endeavour should be exerted to keep them moist and cool and no better spot can be found than in cold frames facing north. The frames should have an ash bottom and plants should be well spaced out. The ash bed is particularly to be recommended for this is of the greatest assistance in preserving a moist atmosphere and also prevents worms from entering the pots through the drainage hole.

THE SALMON PINK-FLOWERED FRILLED CYCLAMEN MRS. BUCKSTON.

CYCLAMEN BLACKMORE AND LANGDON'S GIANT WHITE.

By the beginning of October the plants will probably begin to shew flower buds, which is one of the great advantages of sowing at the present time, for the plants thus become true winter flowerers, a period when they are most valuable. Unless it is desired to retard the flowering, preparations should be made in late September or early in October for housing the plants. This may, however, be deferred by allowing them to remain in the frames for a few weeks longer, but care must be taken that they do not become frosted during an exceptionally cold night. When housing, give the plants a good light place in an airy greenhouse, if possible on a bed of ashes or shingle. Do not allow the temperature to run too high at first. Remember they have been in cold frames for an extended period and so any sudden rise is likely to be injurious.

Once they have become acclimatised to their new quarters, feeding with liquid manure may begin

and may be varied from time to time with a pinch of artificial or chemical fertiliser. Be sure, however, that these are always used under normal strength, lest the roots be burned. Take care, when either dead leaves or flowers are removed, that this is done by pulling and not cutting off. Cutting leaves a tag of the old stem attached to the corm which is apt to rot and may spread the decay to other stems or even to the corm itself. Watering, too, is a matter that needs care. To guard against decay, the water should always be poured upon the soil at the side and in small quantities at a time, so that it never floods the centre of the corm. All watering should be performed early in the day so as to give the plants as good a chance as possible to dry before night. After the plants have been housed in autumn, shading may usually be dispensed with, until after flowering is over. The weak autumn sunlight proves beneficial to the health of the plants and buds.

BULBIST.

THE GENTIANELLA

WITH all due deference to the late Mr. Reginald Farrer, I cannot bring myself to accept the name of *GENTIANA GENTIANELLA* for this old favourite of our gardens. Also, after many years of experience with this plant, I cannot agree that a soil rich in lime is essential to its well-being or free flowering. Personally, I incline to the view that the presence of certain soil bacteria is really the essential factor in flower production. As far as I can see, the plant lives well enough in almost any garden, but in some districts, and especially in town gardens, where the air is impure and where probably considerable quantities of sulphuric acid are precipitated with the rainfall, the plant produces nothing but empty calyces, whatever the blandishments (in the way of special soil mixtures) used by the anxious cultivator.

The only effective remedy for this non-flowering so far as I know, has been the introduction of soil from a garden where this Gentian flowered

freely. This resulted, in practically every case, in the production of at least a few flowers during the first year after this soil, presumably full of the necessary bacteria, was introduced. In some gardens where the air was tolerably pure the good effect has continued, but in others the plants reverted to "blindness" after the rainfalls of the winter, charged heavily with impurities, had most probably put an end to the beneficent activities of the bacteria I presume to have been present in the soil introduced.

Anyone at all well acquainted with the R.H.S. gardens at Wisley must have seen this Gentian flowering profusely in the almost lime-free soil there; in fact, the authorities at Wisley will be almost certain to attribute this freedom of flowering to the absence of lime. On the other hand, at Stevenage, from whence I write this note, this Gentian flowers every bit as freely in a soil so full of lime that Rhododendrons are impossible in the district. Again, in a garden at Caterham, well known to me for many years, this plant is

marvellously free on a stiff, clayey soil charged with chalk and freely enriched with leaf-mould. Fourthly, I know of a garden at East Grinstead, on the Lower Greensand formation, where Heathers thrive, and here again the Gentian flowers well without any special preparation or feeding of the soil. I could continue to quote further instances of the thriving and flowering of this plant with lime or without, but I believe enough has been said to prove that my contention is at least worthy of further consideration and trial by those who have hitherto failed to flower this singularly attractive plant.

Now for the name! *Gentiana acaulis* of Linnæ appears to cover several closely allied plants, and the nomenclature of these various forms is at least confusing. Mr. Farrer tackled this confusion manfully, but he has not succeeded in making his final ruling acceptable to me. For instance, his assumption that this plant might possibly be a hybrid seems to be bad. The plant, as I have proved on several occasions, reproduces absolutely true to type from seed. This, one would scarcely expect from a plant of hybrid origin, although this might be the "exception that proves the rule." The name *G. acaulis*, L., covers among others *G. excisa*, Presl., and *G. Kochiana*, Perr. et Song. Now *G. excisa* in nature is generally found upon non-calcareous formations. Moreover, it is the form that descends into the valleys, which should show certain powers of adaptability and help materially to make it easier of cultivation in our lowland gardens. Lastly, a fact of some importance, I have seen, in the course of my wanderings, plants of this species which I was assured were collected upon moorlands in Northern Germany and in what used to be, and is now at last again, Denmark. I hunted through one of these localities, alas! in vain, but I did find *Anemone vernalis* in quantity, a congener of our plant in its mountain home. Finally, I found that the plant was well known to the Low German-speaking peasantry, who, judging by their gardens, could scarcely be called gardeners. However, they knew the plant at sight from illustrations, and offered to point out places where they had seen what they called "Hamborger Mützen." This seemed to prove to my mind the existence of a lowland form of *G. excisa*, and this I believe to be the true origin of our garden plant which Mr. Farrer would wish to be known as *Gentiana Gentianella*, a name I hold to be particularly unsuitable, as in most Latin tongues the suffix "ella" implies a diminutive, whereas our plant produces one of the largest flowers found in the genus and is by no means the least in stature. I believe the majority of gardeners will be with me in wishing to continue to call this plant by its well known garden name of *Gentiana acaulis*, which, after all, appears to be a collective designation, and if they wish to call it by a more or less anglicised name, use the name "Gentianella" as such, unless they prefer to call the plant the "Stemless Gentian," which, if inaccurate, is quite as usual nowadays in my experience.

In conclusion, I do not wish to imply that this Gentian may not do better in many gardens with liberal feeding. Crushed bone and fish guano, shoddy and old hot-bed manure incorporated with the soil are acceptable to the plant, while full exposure to the sun and free applications of the watering-pot during dry spells in summer are of undoubted assistance. Very firm planting is absolutely necessary and, as the plant has a habit of growing out of the soil and exposing a neck, a top-dressing carefully worked into the tufts and well watered in in the autumn is advisable. I firmly believe that people who have failed to flower this Gentian so far will achieve

at least a temporary success by importing a sack of soil from a locality where the plant is known to flower freely, and either mixing such soil to the extent of 50 per cent. with the soil of their own gardens or, in very smoky districts, by entirely filling a small bed with the purchased soil, enriching the same in the manner indicated by all means, and so making assurance doubly sure.

W. F. TH. INGWERSEN.

No botanist is infallible, and the late Reginald Farrer would have been one of the last to claim infallibility for his deductions, and it is quite

likely that he was less thoroughly acquainted with *Gentiana exisa* than with the other species lumped together by Linnaeus—also far from infallible!—as *G. acaulis*. Mr. Ingwersen's theory of the origin of the plant is very feasible, and it would be well if the matter could be satisfactorily cleared up once and for all. It seems to us that the plant would then be best described as *Gentiana exisa* var. *Gentianella*. Certainly it seems undesirable from a botanical standpoint to revert to the name *acaulis* which formerly introduced so much confusion. (Ed.)

THE GREAT AUTUMN ROSE SHOW

THE Autumn Show of the National Rose Society, held on September 20 and 21 at the Royal Horticultural Hall, was, in the opinion of some good judges, the best show ever put up by the Society, and therefore in all probability the best ever set up in any country. It was certainly an immense improvement upon the Summer Show, which, it will be remembered, had very adverse conditions to contend against. The Hall in Vincent Square was on the first day of the Show altogether too small to contain in comfort the crowd of enthusiasts that almost fought its way into it, and many of the visitors could have received only a few confused impressions of a magnificent exhibition. It is plainly evident that the Society will have seriously to consider the question of a more commodious venue for the corresponding meeting next year.

The "representative groups" of Roses were more popular than ever with the trade growers,

who have fully realised their immense value in shewing off the possibilities as well as characteristics of the different varieties. The principal class was so well patronised that the whole length of the hall could not accommodate the exhibits, and there was an overflow into the body of the hall.

This magnificent array of the finest Roses the world can produce at this season made a memorable display. It seemed almost as though the exhibitors had entered into an agreement to co-ordinate their arrangements so that a pleasant uniformity, without monotony, should be obtained. There were half a dozen of these large exhibits along the wall space and, while no two were alike, each blended harmoniously into its neighbour.

The judges had no enviable task, and if they had recourse to pointing, half points must have been employed, because the merits of the principal collections were remarkably even. There was a certain similarity in the method employed by

the two most successful exhibitors, and it seemed that the first prize was won by Mr. T. Robinson on account of the extra lightness in his arrangement, though, as we have already remarked, the merits were remarkably even. Both collections were exceedingly fresh and bright. In Mr. Robinson's group the tall stands of Emma Wright, Ophelia and Golden Emblem were excellent in this respect. Though filled with very good blooms and in generous quantity, the stands of Colonel Oswald Fitzgerald, and K. of K., while splendid in themselves made dark patches which just prevented the group being ideal. His smaller masses of Christine, Elegante and the deliciously fragrant Walter C. Clarke were also very delightful.

In the second prize group of Messrs. S. McGredy and Son the blooms were also exceedingly fresh and perfectly timed and pre-eminent in their colour associations. The stand of The Queen Alexandra Rose, for example, was vividly beautiful and in perfect harmony with Lady Pirrie and Golden Emblem. The last named and Christine were most beautifully coloured; while Isobel, Admiration and Los Angeles were also of great merit. Messrs. A. J. and C. Allen were third, and they had a very pleasant style of arrangement. The colours of the large stands of Independence Day and of Padre were magnificent. Arches of Ophelia, Mrs. Henry Bowles and K. of K. associated with sprays of Rosa Willmottiae and R. sericea pterantha in the collection of Messrs. Chaplin Brothers were very effective. Besides good vases of Mrs. Henry Stevens, Los Angeles and Edith Cavell they had a small vase of the uncommon green-flowered Rosa viridiflora. Messrs. Alex. Dickson and Sons well illustrated the great

REMARKABLY COLOURED—ROSE SHOT SILK.

THE GOLDEN YELLOW BETTY HULTON.

decorative value of their varieties Betty Uprichard and Lady Inchiquin, of which they had magnificent stands. Messrs. Bees had a large massed arrangement of their Independence Day of glorious colouring.

NEW ROSES.

There was no shortage of new Roses and almost all the varieties put up for award seemed desirable garden varieties. We took the opportunity of looking over the new varieties at leisure on the morning of the second day and it must be confessed some of the varieties took on new qualities when thus seen under more natural conditions—for buds and blown flowers were then to be seen—and, of course, the Rose is really a morning flower.

Shot Silk.—This variety was shown at Regent's Park last summer, when its glowing colouring was commented upon. It is a rather loosely made, rounded bloom carried well on stiff stalks. The colour is orange rose with a golden yellow base. Gold medal. Shown by Messrs. Alex. Dickson and Sons.

Betty Hulton (H.T.).—A rich yellow Rose of long shape and rather loosely made, shewing a good deal of Tea blood. There is a suggestion of pale orange in the heart of the blooms. The foliage is good, but it is not at all stout of petal. Gold medal. Shown by Messrs. Alex. Dickson and Sons.

Aurora.—In many ways this is a good primrose yellow counterpart to Nur Mahal, for it belongs to the same section (Hybrid Musk) and is also free flowering. Certificate of merit. Shown by the Rev. J. H. Pemberton.

Earl Beatty.—In quantity, as this Hybrid Tea Rose was staged, it is quite effective. The closely made, fully double flowers are of crimson colour. Shown by Messrs. Chaplin Brothers.

Nur Mahal.—This semi-double free-flowering Hybrid Musk variety has been on view regularly throughout the year, when many have admired its bright colouring. It had previously been awarded the certificate of merit. Shown by the Rev. J. H. Pemberton.

Richard E. West.—A useful yellow Hybrid Tea variety bearing medium-sized blooms on good stems. Shown by Messrs. Alex. Dickson and Sons.

Victor Waddilove.—A good double Hybrid Tea variety of rich pink colouring. The foliage is quite small, very clean and of a good green. It should prove to be a good variety for all purposes and is wonderfully fragrant. Certificate of merit. Shown by Messrs. S. McGredy and Sons.

June Boyd.—A most charming Hybrid Tea variety of good size and form. The delicate golden buff colour is lightly overlaid with rose purple. The blooms are fully double and the broad petals are substantial. It has small, clean, purplish foliage. Shown by Messrs. S. McGredy and Sons.

Mrs. J. Heath.—A lovely creamy yellow Hybrid Tea Rose flushed with pink, especially in the heart of the bloom. It should be a good garden Rose. Shown by Messrs. S. McGredy and Sons.

Margaret McGredy.—This may well be termed The Queen Alexandra Rose of more scarlet colour and without, or with very little, golden yellow. Consequently it is a bright and showy variety. Many thought that if any gold medals were awarded this should have had one. Certificate of merit. Shown by Messrs. S. McGredy and Sons.

Mrs. S. Paton.—A charming, richly coloured rose pink Hybrid Tea variety with a suggestion of golden yellow in the reverse of the petals. The buds are of perfect shape, but it becomes a flattened bloom when fully expanded. Shown by Messrs. S. McGredy and Sons.

Joan Waddilove.—A small and rather thin, but very striking Hybrid Tea Rose. The golden reverse

is very prominent and sets off the light flushing of rosy-purple. Shown by Messrs. S. McGredy and Sons.

Mrs. C. W. Edwards.—A splendid, large Hybrid Tea Rose, with broad, substantial petals which rolled back gracefully. The colour is a deep rose and the stems and foliage are very good. Shown by Messrs. S. McGredy and Sons.

Lady Sackville.—The darkest of the new Roses. The rather small rounded blooms have a lumpy appearance and are only moderately fragrant. Shown by Messrs. S. McGredy and Sons.

Sadie.—A vigorous Hybrid Tea variety bearing well formed, slightly fragrant blooms of creamy orange colour, lightly shaded with apricot. The foliage is clean and good. Shown by Mr. George Prince.

Fanny Oppenheimer.—The most brilliant Rose in the whole Show. The form is not first-class, but it would be showy in the garden and a very telling variety in the classes for decorative Roses. The buds are of good shape, but they open loosely, though the petals are substantial. The brilliant cardinal-coloured blooms are lightened by a golden base. Certificate of Merit. Shown by Messrs. S. McGredy and Sons.

Phyllis Bide.—This is a quaintly beautiful perpetual-flowering Rose. It bears quantities of small, loosely made, almost double flowers of pale golden yellow, broadly tipped with pale rose. The foliage is very good and altogether it is a charming and uncommon variety. Certificate of merit. Shown by Messrs. S. Bide and Sons.

Lady Charmion.—A rosy-cerise Hybrid Tea Rose of medium size, apparently very free and would be effective in the garden. Shown by Messrs. Bees, Limited.

Etoile d'Hollande.—This very meritorious Hybrid Tea Rose was sent out in 1921, but is not yet in general cultivation. The very fragrant blooms are of moderate shape, medium size and rich crimson maroon colour, with lighter tips. The foliage is substantial and it appears to be a variety that would shew up well during adverse weather. It is worth growing for its fragrance alone. Shown by Messrs. H. Morse and Sons.

Mabel Turner.—A very good Hybrid Tea variety, fully double and of long pointed shape. The broad petals are a medium pink shade and have silvery reverses. The foliage is clean and good. Certificate of merit. Shown by Messrs. Hugh Dickson, Limited.

Oliver Meer.—A Hybrid Tea Rose recommended for the garden and for exhibiting. It is a medium-sized, shapely bloom, flushed with peach pink on dull white ground. Certificate of merit. Shown by Messrs. Hugh Dickson, Limited.

Alice.—A pretty dwarf Polyantha variety of fair size and old-fashioned rose-pink colouring.

It appears to be very free and should prove to be a useful bedding variety. Shown by Messrs. D. Prior and Sons.

Treversa.—A deep pink Hybrid Tea variety, fully double and of long shape. It is said to be

THE DELIGHTFULLY COLOURED JOAN WADDILOVE.

very free flowering. Shown by Messrs. D. Prior and Sons.

Mussolini.—A very beautiful Hybrid Tea variety of rounded form. It is recommended as an all-purposes Rose and is said to be of vigorous habit. The fully double flowers which are prettily flushed with peach-pink have a golden buff reverse. Shown by Messrs. D. Prior and Sons.

F. J. Looymans.—An excellent Hybrid Tea variety. The shapely blooms are fully double, of bright orange colouring with a hint of apricot, and are borne on long straight stems. The neat foliage is a shining green. Shown by Messrs. D. Prior and Sons.

Elvira Aramayo.—A small, showy, vigorous garden Hybrid Tea Rose of India red colour, with a suggestion of cerise. Shown by Messrs. D. Prior and Sons.

Allen Chandler.—The Cory Cup, which is offered for the best new Climbing Rose of the year and has been open for competition at all three shows of the Society, was awarded to this variety, shown by Mr. George Prince. It is a very attractive and free-growing climber, producing plenty of trusses of semi-double flowers of bright scarlet colour, slightly suffused with velvety maroon and about 2 ins. across. It is very pleasantly fragrant.

The conclusion of the report of this great Show with pictures of some others of the New Roses exhibited will appear in our next issue.

HARDY FLOWERS AT VINCENT SQUARE

THAT autumn, close upon us, was fully evident from the flowers which predominated at the Royal Horticultural Society's Hall, Westminster, on September 18 last. As on a fortnight ago, Dahlias filled large spaces and Gladioli were numerous, while chief among general border flowers were Kniphofias, Michaelmas Daisies and perennial Sunflowers. Carnations, including the useful *Dianthus Allwoodii*, were displayed in their wonted quantities and quality. Orchids increased a little and, in anticipation of the Autumn Show, two days later, Roses were set up in generous quantities. But as this flower will then "hold the stage," we content ourselves with mentioning their presence. Dahlias had their great day a fortnight ago and the new varieties are described below. Mr. H. J. Jones, however, annexed a gold medal for these flowers with a brilliant exhibit in which the only fault was a certain sense of disconnection between the towering pillars of the background and the vases in front. Mr. Cobb's exhibit was composed of novelties of his own raising, prominent among which were *Vive la France*, which was selected for trial a fortnight ago. Mr. J. B. Kiding had an interesting group with some very pretty stands of the small Decorative sorts. Messrs. Carter Page again had a good show; so had Messrs. Cheal.

Violas were again shewn very well indeed by Mr. H. Yandell and also by Messrs. Artindale and Co., who included some particularly good Gladioli

and a brilliant Kniphofia named *The Rocket*. Kniphofias were especially effective as a background to the group arranged by Mr. M. Prichard who, along the front, had several good garden Pinks. The double-flowered B. O. Prichard and the singles Schuman and Rosette Cense were very desirable.

Although by no means new or rare, a large vase of *Liatris pycnostachya* was very effective in an exhibit by Mr. W. Wells, Junr., while near by Messrs. Harkness and Sons included the yellow *Guilfordia* E. T. Auderton in a particularly effective group. Many of the named *Pentstemons* set up by Messrs. Wm. Curbush and Sons were well worth growing.

In the annexe Mr. E. R. Russell had a pretty little group of *Clematises* and, besides the large-flowered garden varieties, he shewed *Clematis tangutica*, which bears such uncommon rich yellow pendulous little flowers. In the corner by the annexe Messrs. Carter and Co. were very successful with their arrangement of some splendidly grown pot plants of *Lilium speciosum* and its varieties.

Pentstemon Kellermanii, associated with the purple foliage of *Prunus cerasifera* Pissardi made a restful and pleasing vase in the collection of Mr. F. J. Wood, who also shewed long growths of *Physalis Francheti*. Mr. S. Morris shewed splendid spikes of *Montbretias*, but some excellent new ones were under seedling numbers.

A welcome addition to the general exhibits at the Hall were the magnificent pot fruits shewn by

Messrs. T. Rivers and Son and Mr. J. C. Allgrove. Both were models of expert cultivation and of fruitful little trees. In Messrs. Rivers' group the fruits of such Plums as *Coe's Golden Drop*, *Late Orange* and *Coe's Violet* had a very tempting appearance, while their Peaches included *Princess of Wales*, *Lady Palmerston* and *Sea Eagle*, which fruits so well out of doors in the western counties.

Chief among Mr. Allgrove's collection were the trees of Allgrove's *Superb Plum*, which may be termed a coloured *Jefferson*, as it is otherwise similar to that fine variety. He also shewed *Early Transparent Gage*, *Crimson Galarde Peach* and heavily-fruited sprays of *Rubus lauratus*.

Messrs. Daniels Bros. again shewed their September *Black Currant* and the large fruits were as firm and plump as a fortnight ago, thus well illustrating the great value of their variety. They also staged a few dishes of Apples and Pears.

From the Guild of Blind Gardeners came a most praiseworthy collection of seasonable vegetables, with a few flowers. The vegetables were tully equal to the prize-winning examples at many country shows and included Potatoes, Beet, Onions, French and Runner Beans and Vegetable Marrows.

NEW AND RARE PLANTS.

Kniphofia Royal Standard.—This is a graceful and effective "Red-hot Poker Flower." The spike is of medium size and the bright coral of the upper two-thirds, which is composed of unopened

A STUDY IN ORANGE AND YELLOW, THE VERY EFFECTIVE NEW MONTBRETIA JESSIE

THE REMARKABLY LATE AND FINE BLACK CURRANT DANIEL'S SEPTEMBER BLACK.

flower buds in various stages of development, contrasts well with the primrose yellow of the fully open flowers below. Award of merit. Shewn by Mr. M. Prichard.

Montbretia Jessie.—A beautiful variety of these popular plants. It is a rather more than medium-sized flower, nearly round and of yellow ground colour, evenly stippled with orange yellow on two-thirds of the petals, giving the appearance of a yellow zone. Award of merit. Shewn by Mr. S. Morris.

Montbretia The Princess.—This variety is of similar type to the foregoing and differs in its richer colour and in the petals having a crimson lake blotch at the base, within the yellow zone. The outer colour is a deep orange. In both varieties the outer surfaces of the petals are heavily flushed. Award of merit. Shewn by Mr. S. Morris.

Pyrus earlhamensis.—The committee must have been in generous mood when they recommended the award to this tree. To all garden intents and purposes it is a poor imitation Cider Apple. We have just recently seen hundreds of Cider Apple trees in Devonshire of superior garden value. The orchard trees were of much more graceful habit, bearing more freely equally highly-coloured fruits. Award of merit. Shewn by Mr. S. Morris.

Cypripedium Godefroyæ var. Len-cochilum.—This is a very beautiful variety of this well known "Lady's Slipper Orchid." Like the type it is of sturdy compact habit and has green leaves. The substantial flowers are the colour of old ivory, freely spotted with bright chocolate. Award of merit. Shewn by Messrs. Cowan and Co.

Lælio-Cattleya Aureole var. Renown.—A strikingly handsome Orchid. The sepals and petals are of rich yellow colour which continues part way along the lip. The frontal portion of the expanded lip is of rosy purple colour lined with gold towards the throat. Award of merit. Shewn by Mr. Pantia Ralli.

Vuylstekeara medea.—This member of the recently constituted group is a cross between *Odontioda Zenobia* and *Miltonia Charlesworthii*. The sepals and petals are of rosy crimson colour lightly flushed with maroon. The basal half of the distinct lip has the same colouring while the broadened and slightly waved outer half is prettily mottled. Award of merit. Shewn by Messrs. Charlesworth and Co.

NEW DAHLIAS.

At their meeting the Joint Dahlia Committee found an almost embarrassing number of novelties before them, and, of these, selected the following for trial at Wisley. Dahlia raisers seem to have short memories, for, again, several of the novelties have to be re-christened. It was made clear that unless the raisers guaranteed to send plants to Wisley next spring their novelties would not be considered.

Reading Star.—An exceedingly showy Star Dahlia of bright crimson colour, prettily tipped with maroon. Shewn from the University College Gardens, Reading.

Lydia.—Another valuable Star Dahlia. It is rather larger than most of this type and of good yellow colour. Shewn by Mr. Chas. Turner.

Snowdrift.—A large, perfectly formed show Cactus Dahlia. When first open it is a good white, but the blooms seem soon to discolour. This and the two following were shewn by Mr. H. Shoemith.

Lenny.—A medium-sized Decorative variety of

Beacon.—Although described as being a Decorative variety this is much like a coarse Cactus Dahlia. The colour is crimson-magenta.

Vera.—A medium-sized Decorative of compact habit and pointed florets. The colour is scarlet flushed with crimson, except at the white tips.

THE BRIGHT VELVETY CRIMSON MINIATURE PÆONY-FLOWERED DAHLIA VIVE LA FRANCE.

rather thin texture. The pale yellow ground flowers, flushed with rosy-purple are, however, very pretty.

Winnie Hardy.—This is a very decorative Cactus variety of medium size. The rolled florets incurve and are of deep rosy-mauve colour tipped with gold.

Polar Bear.—A large, shapely Decorative variety of high merit. It is a well formed, pure white variety. Shewn by Hon. Vicary Gibbs.

Thursa.—A pretty Miniature Decorative variety with pointed florets of bright scarlet colour. This and the four following were shewn by Messrs. J. Burrell and Sons.

Gwynne.—A small Pæony-flowered variety of rich velvety crimson colour, which is a deeper shade in the centre of the flower.

Violetta.—A Pæony-flowered variety of rather more than average size and bright mauve colour.

Emblem.—A well formed Decorative of rosy-mauve colour with an occasional gold line and golden at the tips.

Sylph.—A large Pæony-flowered bloom of sparkling texture and flushed with lavender.

Rocket.—A large exhibition Cactus with rolled florets. The colour is rosy mauve with a paler centre. This and the following were shewn by Messrs. J. Stredwick and Son.

Dot.—A pretty little Collarette. The white florets have a deep crimson line running up each side towards the tip and the crimson quills alternate with white.

Maggie.—A broad-petalled Decorative of velvety crimson colour, lightly tipped with white.

Phosphorous.—A very large yellow single Dahlia.

Rector.—A mauve-flushed Decorative with a few chocolate spots.

L. Hancock.—A large, flattish Decorative, well-set-up and of pale scarlet colour, lightly flushed with crimson.

Mrs. E. G. Cant.—A large Decorative of pale orange-buff colour, which becomes flushed with rose. It is somewhat star-shaped.

Lucien.—A good primrose-yellow Decorative of large size.

Nero.—A perfectly formed rich crimson-maroon Pompon variety. Shewn by Messrs. J. Cheal and Sons.

NEW FRUIT.

Apple George Neal.—This seedling Apple was shewn last year, when an award of merit was recommended, conditional on the tree passing an inspection by the Sub-Committee, which now reports that it is of good habit and growth and a fine cropper, so the award becomes substantive. The dish of fruits submitted to the Committee did not survive the ordeal, so we may conclude that the flavour is satisfactory. As we remember it, the new Apple is in size and shape much like Lane's Prince Albert and of attractive appearance. It is recommended both for the dessert table and for kitchen use. Shewn by Messrs. R. Neal and Sons.

FORTHCOMING EVENTS.

October 2.—Royal Horticultural Society's Great Autumn Show, to be held at Holland Park Hall, Shepherd's Bush (three days).—Royal Caledonian Horticultural Society's Meeting.

October 3.—Lewes Horticultural Society's Meeting.

CORRESPONDENCE

IRIS PRICES.

WHETHER prices are too high depends on whether they are fixed by supply and demand—as "Siri" considers—or are arbitrarily inflated—as I do. As to supply, I cannot believe that there is any appreciable number of varieties ten years old, and upwards, of which an individual grower could not supply fifty plants if he expected that that number would be required. That it can be done is shown by the fact that Continental growers quote prices per ten varieties only one or two years in commerce, and per 100 of older varieties, even of expensive sorts, such as *Souv. de Mme. Gaudichau*. Either I have been fortunate in my experience of Continental plants, or "Siri" has been unfortunate. For the past three seasons I can supply the following comparison. Varieties obtained from Continental growers, 39; flowered first season, 32 = 80 per cent. Varieties obtained from English growers, 27; flowered first season, 7 = 25 per cent. I have omitted one set of Continental plants which were delayed eight weeks in transit and suffered accordingly, and some *Ricardii* hybrids planted late this spring.—B. R. LONG.

AUCUBA SEEDLINGS AND OTHERS.

MANY years ago I had some of the first berries ever produced in the United Kingdom, from the celebrated garden of Mr. W. E. Gumbleton, and therefrom I got two fine varieties, one I call Golden King, the other Green Queen. The former has a very fine robust habit and I have many bushes of it, the other bears fruits, but its growth is very poor. I have also (from Swiss berries) some other distinct varieties, as in that climate seedlings come in quantities round and about the parent plant, while here I never get one. Another seedling, very far removed, is *Asparagus*, which appeared at the foot of a *Gooseberry* bush, quite rooyds. from the *Asparagus* bed. It passed through some misadventures and now has become a giant! Last year's growth was 8 ft., and to-day's measurement is 8 ft. 9 ins., and we ate some early growths as well. This success is all due to salt, as one day I got strong pickle from the meat butt, and said, "Kill or cure, I'll try it." The success of this big dose is astonishing and points to the impossibility of giving too much salt.—J. H. POE, Capt., *Riverston, Nenagh, Tipperary*.

GALANTHUS CILICICUS.

IT is pleasant to observe that this autumn-flowering *Snowdrop* is again offered. I do not remember to have seen it catalogued for some time. It is, I have found, the most reliable of the autumn-flowering *Snowdrops*, though with me, after the first year of importation, it did not flower until November, and in some seasons even as late as early December. It is quite a pretty little *Snowdrop*, not, of course, superior in beauty to our own *G. nivalis*, but quite welcome in the rock garden or the front of the border, though rather too precious for any place where it would run any risk of destruction by careless hands or the encroachments of rampant plants.—S. ARNOTT.

THE TULIP IN SUBURBIA.

THE accompanying photograph, taken in my own garden, shews, I think, that Darwin and May-flowering Tulips can be grown fairly well in a small suburban garden under certain conditions. To get the best results, however, when growing them in the same confined space year after year, as I have done for seventeen years, it is essential that the soil should be annually replenished by the addition of good fibrous loam. Tulips are "gross

feeders," so stable manure should be incorporated with the soil, but placed well down so that the bases of the bulbs do not touch it when planted. Failing stable manure—now difficult to obtain—I find

PART OF A GARDEN OF TULIPS.

basic slag and bone meal a good substitute, but there is no real substitute for stable manure. Towards the end of October is a good time for planting, when the soil is in a nice friable condition. If planted early they come through too soon and severe March winds somewhat batter the foliage, but they are quite hardy and will survive even Arctic weather.

The man with a "tablecloth" garden desires to cultivate a little of everything, with the result, I am afraid, that he rarely produces anything of outstanding merit. In my own case I grow Tulips between rows of *Roses*, *Phloxes*, etc., so that when the Tulips are over in mid-May there is still something to come in the summer months. The bulbs should be lifted in July, when the foliage has decayed, dried and stored for replanting. This is a slow process requiring patience, but the amateur gardener has his *quantum* of patience!—W. F. S., S.W.17.

STRAWBERRY CULTURE.

I HAVE read carefully the comments of Mr. Engleheart respecting my notes upon Strawberry cultivation. His method differs from mine. That his method is successful is evident by the results achieved, but I claim that the method of culture I advocated on page 442 has proved successful too. We are thus brought face to face with the well known fact that success in horticultural practice can be achieved in more ways than one. I hope, therefore, that Mr. Engleheart will pardon me for explaining my system of propagation in greater detail. I advocate that runners should be taken from one year old plants because such plants still possess the vitality of youth. It seems but logical to assume that young stock raised in this manner will partake of the vitality of their parents. So far Mr. Engleheart and myself may be in agreement. At this stage, however, a difference in practice arises. He propagates from yearlings

which have not been permitted to fruit. I propagate from yearlings which have fruited. I do so with the object of reducing the number of "blind" or sterile plants in the plantation. That such sterility is hereditary in some cases I have proved by experiment. As fertility or sterility can only be proved

by growth, it seems more in accord with reason to reject the runner of the sterile plant. My difficulty in embracing Mr. Engleheart's system is this: I cannot see how the naturally sterile plant is to be discovered when all are artificially made sterile. It may some day be my pleasure to introduce to Mr. Engleheart growers who do not fruit their Strawberries the first year after planting. Some of them are worthy exponents of the ancient craft of horticulture. As I previously stated disagreement with this particular phase of their practice I am not now called upon to defend it. Neither do I regard seriously Mr. Engleheart's criticism of the compost recommended for potting the runners. The runners are only in the pots for a very short period, and any type of sweet soil would meet their requirements. I advocated a light soil because roots are usually emitted freely in such a compost.—GEO. H. COPLEY.

[It is not easy to follow our correspondent's point about sterility. Surely, if one removes the blossom trusses from a plant one knows that it is fertile, and it would be perfectly easy to grub up and destroy plants which never shewed blossom. No doubt "blindness" is a specific disease or a condition brought about by disease; It is certainly transmissible to the "runners."—Ed.]

IRIS CRISTATA.

FEW of the dwarf rhizomatous Irises are so delightful and satisfactory as *Iris cristata*, from the mountains of Kentucky, Virginia and Carolina. Where it succeeds well, as it does in most places, it increases into a spreading mass of short, broad leaves and stems, 4 ins. to 6 ins. or so high, bearing wonderfully large flowers of a charming lilac or violet shade, decorated with a conspicuous crest, one of the features of the *Evansia* section, to which it belongs. It thrives specially well in some gardens and in these it is an object of great beauty

in summer. It appears to like a gritty soil with a fair amount of moisture underneath, but the latter does not appear always to be essential. I have never found it difficult to cultivate, except that slugs were inclined to be troublesome and to crop the

plant to the ground in early spring. It is easily increased by division. It is a comparatively inexpensive plant, but the rather scarce white variety, *I. cristata alba*, is higher in price.—S. ARNOTT.

SELF - SOWN BIENNIALS

TO every amateur who works with his own ten digits and not by the proxy of a professional gardener there comes a time, I fancy, soon or late, when his spontaneous energy is less than it once was, and the passion for muscular toil sensibly abates; when, in short, he is disposed, in respect of garden work, to accept the advice of Mr. Squeers to "moderate his transports." It is then one learns to regard with a preference—half gratitude, half affection—those easy plants which give little trouble—bulbs which come up year after year without abating a jot of their beanty, herbaceous plants which require neither annual manuring nor periodic transplanting, shrubs that want nothing for their well-being but abundance of space, and things, annual or biennial, that see to their own propagation and require on your part nothing more arduous than judicious thinning with the hoe. About these last a word may be permitted by way of suggesting to brother gardeners, whose vertebral column is possibly not the elastic thing it once was, one or two plants of this easy class which will well repay the little trouble of growing them; not so much about annuals, however, as about some half-dozen biennials which are worth while and which require only a first foothold to become permanent denizens of the garden. Though, if it comes to that, there is no lack of desirable annuals with this same valuable quality of permanency; for, however tender and beautiful an annual may be, there is somewhere a country where it sows itself one year to come up the next, where, in other words, it is a weed. *Nigella*, *Centaurea*, *Iberis*, *Nemophila*, *Limnanthes*, *Platystemon*, *Clarkia*, *Alyssum* are weeds in the country of their nativity and may become weeds in any British garden where slugs permit. A biennial, however, is another thing, being, as a rule, of larger stature and more stately habit, and requiring, in consequence, two years to build up its system and complete the cycle of its growth. Two of these valuable biennials, the Foxglove and the Olympic Mullein, have been dealt with lately in *THE GARDEN*, and need now only be mentioned. A third biennial of large size and imposing appearance, which I never sow and yet which I am never without, is the tall Evening Primrose (*Oenothera biennis*). This beautiful and interesting flower has been a standing feature in my garden for ten years and more. It comes up here and there in the borders in unexpected places—often, of course, where it is not wanted, but often also, I must do it the justice to say, precisely where I should have wished it to be if I had thought the matter out. In any case, if it should come where you do not wish it to be, a touch of the hoe is sufficient. On the other hand, should you wish to have it in any spot where it has not chosen to come, few things are so easy to transplant. The endurance of the plant is wonderful. Dry weather or moist, your transplanted *Oenothera*, after wilting for a day or two, will brace up and look as lively as if it had sown itself where you had placed it. The beauty of the Evening Primrose is sufficient to recommend it if it had nothing else, but, for me, one of its attractions is its evident delight in life and growth. I had rather see, for my part, a Dock or a Thistle grow as if it enjoyed life, than the most precious stove or alpine treasure that lingers out

a coddled existence; though, for all that, I do not deny the satisfaction there is in coaxing a sick plant back to vigorous life. Every hospital nurse knows this kind of triumph. But there is no room for coaxing or coddling with *Oenothera biennis*. Wet does not harm it, neither does drought; it seems to prefer exactly the conditions of soil and weather it happens to get. It is subject to no parasites, blights or diseases that I have ever seen. It stands erect without support; or if the wind does happen to twist off a branch or two, these are not missed—there are so many left. But, after all, the distinction of this, as of all Evening Primroses, is that it is a flower of the dusk, one of the far from numerous vespertine group which wake to full activity only when Marigolds, Daisies and other drowsy composites are folding their petals to rest. Night moths, which are so drawn to light in darkness, must certainly frequent the flower, though I do not know which they are. In the latter days of August, when the evenings begin sensibly to lengthen, and the air has an eager tang, which, though pleasant, is a premonition of something more nipping and less pleasant yet to come, my own otherwise modest garden becomes for a time almost flamboyant, lit up as it is from end to end

with Chinese lanterns—that is to say, with lingering blooms of many-coloured single Hollyhocks swinging on their wands to the wind, but chiefly with the vesper lamps of *Oenothera biennis*, which flop open one by one while the light is waning, as if fairy Mrs. Gamp were unfurling their umbrellas. Those who grow these *Oenotheras* must have observed how punctiliously they observe their times and seasons—how, in opening their first blooms, the various plants synchronise (there is no other word) as regards not merely the hour, but the day and the month, possibly even the minute. Scattered plants, separated possibly by considerable distances in a large garden, will burst into bloom with a wonderful unanimity, at the same hour of the same day of the three hundred and sixty-five. Finally, to complete its tale of virtues, this flower has a pleasant fragrance—not obtrusive, but faint and elusive rather, as befits the crepuscular hour, yet sufficient sometimes to cloy the air a little, for the perfume is of the rich exotic kind which we associate with such things as Orange Blossom, Jasmine and Stephanotis. There are, I understand, two strains of *Oenothera biennis*—a good and a less good. I do not know which mine is, but it is good enough for me.

Another fine biennial which may be trusted, when once introduced, to hold its own, is the Giant Sea Holly (*Eryngium giganteum*). I suppose we must regard all the Sea Hollies as unbellifers. But to eyes like mine, which look to the appearances of things rather than to their hidden affinities, this *Eryngium* has the Thistle attributes raised to a high power, except stature, perhaps, for I do not suppose that the height even of luxuriant specimens is much over 3 ft. But the completeness of its holly-like apparatus for self-defence, its mathe-

matical grace and symmetry of shape, and the veined silver of its leaves seem to assign it a place among those things which "none may molest with impunity." One must not, however, in this biennial, look for the steel-blue which is the conspicuous beauty of stem and flower in so many *Eryngiums*. Silver is its metal, not steel, simulation of frosty silver being its outstanding feature, the most successful mimicry of the metal known to me among many silvery plants. I have spoken, erroneously perhaps, of this flower as a biennial, since it might possibly be more correctly described as a triennial. Grown under exceptionally favourable conditions, the Giant *Eryngium* may flower the second year from germination, but I do not think many of mine, if any, do so. In this, the third year of one batch, there has been a great display of flowering heads—leaving many, however, for next year, which, when they come, will, properly speaking, I suppose, be quadrennials. I should not wonder if even these were to leave some flowerless

THE EVENING PRIMROSE, *OENOTHERA BIENNIS*.

plants behind them, to become, in their turn, quinquennials!

No one, I hope, will despise another thistle-like plant which is, however, no Thistle—the Teasel (*Dipsacus sylvestris*): at least, no one will who knows a good thing when he sees it. Years ago I found, on the edge of a neighbouring field, an interesting rosette of prickly leaves, the basement storey of an unrecognised plant, which I thereupon transferred to my garden. In time it grew into a handsome Teasel and became an object of interest to visitors, who would stand before it, absorbed, and propound questions which I could not always answer. They wanted to know how exactly the *fullones* (the cloth-fullers) used it, and I could not tell them, because I did not know myself. Particularly they wondered what use the plant made of those pools of water which collected in the little

cisterns formed by the junction of each pair of stem-embracing leaves, which seemed never to be replenished and yet to be always full. I could only suggest that the Teasel imbibed the liquid secretly and renewed supplies in the night, in allusion to which thirsty propensity, no doubt, the naturalists of antiquity had named it *Dipsacus*. The Teasel is an exceedingly handsome plant and a desirable object in any garden landscape; but to me it has the added value of being an inducement to goldfinches to visit the garden. On that same transplanted Teasel I used to see as many as seven goldfinches at one time, each on a seed cone, head downwards.

SOMERS.

Dipsacus sylvestris is not the Fuller's Teasel, which is *D. Fullonum*. Both are British plants. *D. Fullonum* differs from *D. sylvestris* in that the scales of the receptacle are hooked at the tips.—*Enl.*

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Tomatoes.—Plants growing in the open should be watched closely. When the fruit is approaching the ripening stage it may be gathered and placed in a warm room or greenhouse to finish. Remove any foliage that may unduly obstruct the sunlight from the fruit and make preparations to prevent damage to the plants from early frosts. This is a good season to pick green fruits for chutney and other purposes.

Mint.—A portion of the Mint bed may be cut down to the ground-level. After a few weeks the roots should be lifted, placed in boxes and stood in a warm greenhouse to produce young shoots for the kitchen. If larger quantities are required, a hot-bed will be necessary. After preparing this hot-bed, when the rank heat has escaped, a layer of soil is placed thereon. It is then ready for the Mint roots, which should be covered to the depth of in. with fine soil.

Lettuce.—Winter salads are often in demand, and while it is an easy matter to keep up a supply of Mustard and Cress, the same cannot be said of Lettuce. There are now plenty of plants from the August and early September sowings, and they will require transplanting into frames and on to sheltered borders. Those in frames will need all the air possible, removing the lights on all favourable occasions, but taking care to prevent heavy rains from entering the frames. Damp is the cause of many failures, so it will be necessary from time to time to remove decayed leaves and to keep the soil stirred between the plants. Those planted outside should be about one foot apart. During the next week or two a sowing of Bath Cos, Continuity, All the Year Round and Hammer-smith may be made to produce plants for next spring.

Peas.—These should be examined occasionally for thrips and mildew, and if either are present the haulm should be sprayed with a mixture of Gishurst Compound. If the weather is dry, a thorough soaking of water should be afforded and, where the growths have reached the top of the sticks, the centre of the shoots can be pinched out, which will help the pods to develop.

The Flower Garden.

Spring Bedding Plants.—Such kinds as Wall-flowers, *Myosotis*, *Polyanthus*, *Arabis*, *Cheiranthus*, *Allioni* and other plants are making headway in the reserve garden. They should be kept free from weeds, and the hoe should be in use at frequent intervals. If the Wall-flowers are making a lot of sappy growth, cut round each plant with a spade a few inches from the stem.

Pæonies. The herbaceous varieties are well worth growing, and where beds are devoted to them it may be advisable to lift, divide and replant them. When the soil has become exhausted the plants do not flower freely, so it is intended to grow them again in the same beds the soil should be trenched and liberally manured. The roots must be divided carefully to prevent injury to the crowns, and each piece after division should possess at least four eyes or growing points. Allow ample space between the plants. Here, we usually plant *Gladioli* between, which furnishes a display later on when the Pæonies are finished. Frequent disturbance is not advised, and this

operation ought only to be resorted to when the plants cease to give a good account of themselves.

Cuttings.—If a quantity of cuttings were inserted in cold frames as advised in a previous note, the majority will have formed roots and, in consequence, more air may be admitted. Keep the soil just moist, remove all weeds and any dead leaves to check any tendency towards damping off.

The Hardy Fruit Garden.

Plums.—These fruits are not grown in small gardens to the extent their merits deserve. They are invaluable for culinary purposes, for preserving and as dessert. A few varieties, no doubt, require a wall to bring them to perfection, but the majority can be successfully grown in orchard or garden. When planted against a wall the Plum is not particular as to aspect, and by judicious planting a succession of fruit may be obtained for dessert. Good drainage is essential, and if the soil is poor, a quantity of loam and a sprinkling of lime may be added. A few good Plums for walls embrace *Coe's Golden Drop*, *Jefferson*, *Green Gage*, *Kirke's*, *Lawson's Golden Gage*, *Denniston's Superb* and *Reine Claude de Bavay*. Fan-trained trees give excellent results. For planting in the open, standard trees are recommended, and suitable varieties are *Czar*, *Victoria*, *Pond's Seedling*, *Early Orleans* and *Monarch*.

Wall Trees.—Any trees, such as Peaches and Nectarines, that may be required for replacing old specimens or inferior varieties should be chosen and planted as soon as possible. Early planting while the soil is still warm is a great advantage, and there is less danger of the trees failing.

Fruits Under Glass.

Cucumbers.—Plants put out for producing a winter crop are making headway, and every endeavour should be made to destroy white fly and other pests, or progress will be retarded. A special preparation for white fly ought to be used for fumigating to keep this difficult pest in check. Sturdy short-jointed growth is desirable, and this can be brought about by careful ventilation and by maintaining a buoyant atmosphere not too heavily charged with moisture. The temperature should be about 65° at night with a rise of 10° during the day. Pinch the growths frequently and do not overcrop the plants. Afford light top-dressings of soil as the roots come to the surface, and never allow them to suffer from drought. If mildew appears, dust the leaves with sulphur.

Fruit Houses.—In many gardens it is necessary to utilise these for *Chrysanthemums*, etc., during the autumn and winter months, and often the leaves of Peach and Nectarine trees are removed prematurely in consequence. This should be avoided and boards or planks should be placed over the borders on which to stand any plants so housed.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Late Potatoes.—As soon as the green disappears from the foliage of late varieties of Potatoes they will be better lifted, as disease may attack them even at that advanced stage. Grade the tubers as ware, seconds and chits. Select sufficient seed

from the seconds and expose them for a week or two before storing them in trays or regular seed boxes in a cool, airy structure. Take care, however, that the tubers while exposed are not damaged by an early frost. Pitting is quite the best method of storing "ware," as table Potatoes are called by the trade, but the top of the pit must be left exposed, save for the straw lining, until the tubers have "sweated out." Remove and burn the haulms promptly. Left on the ground, they tend to perpetuate the spores of the common potato disease.

Mushrooms.—Mushrooms have been abundant in the open of late, in localities favourable to their development; reliance must now, however, be placed on artificial cultivation. Collect sufficient horse droppings as they become available. Throw them into a conical heap and when fermentation becomes active, re-form them into another heap, similar in shape, and repeat the procedure yet again. When the materials have fermented the third time, arrange them in a layer, which remains 1 ft. deep after it has been beaten firm with the back of a fork. Insert pieces of the Mushroom spawn at regular distances and coat the bed with a thin layer of fresh, sifted loam. Cover the whole with a layer of straw to conserve the moisture. Should drying winds prevail, syringe the walls and floor occasionally. In this writing, I am thinking of a regular Mushroom house, but Mushrooms can be successfully grown in any structure from which light is excluded and where a close atmosphere is maintained.

Brussels Sprouts.—Plants resulting from an autumn sowing, or an early sowing under glass will now be turning in for use. The whole crop should be overhauled and all decayed and semi-decayed leaves removed, also any leaves towards the base, even though healthy. This will allow the admission of an additional amount of light and air, to the benefit of the swelling Sprouts.

Fruits Under Glass.

Early Vines.—Vines which it is intended to start before the end of the year should—if they have become defoliated and the wood ripened—be pruned without further delay, cutting the laterals back to within two buds of their base. The house should then be thrown open night and day; this will send the Vines to rest for a time, after which they will the more readily respond to a little pressure when forcing commences.

Late Vines.—In houses where fruit is hanging, every precaution should be taken to prevent the deterioration of the crop. A comfortable buoyant atmosphere should be maintained by judicious ventilation and the application of fire heat. These conditions cannot be obtained where—as is too often the case—the house is almost filled with *Chrysanthemums*. A moderate quantity of rooted *Geranium* cuttings in boxes is a different thing. It should be remembered that next to perfect flavour, the great desideratum in a bunch of grapes is perfect "bloom," and this is only obtainable under ideal conditions.

Melons.—The season for Melons is now all but over and little can be hoped from fruits that are not approaching a state of ripeness. Keep up a brisk temperature and admit a very little air on all favourable occasions. Should the weather prove wet and unless, it will be advisable to cut any fruits that are nearly ripe and to place them in a warm room to finish off.

Vegetables Under Glass.

Cucumbers.—See that the shoots are well thinned out so that plants and fruits may get as much as possible of the now decreasing light. Less moisture will now have to be applied both at the root and in the atmosphere, still there must be no drying-off, as stem, leaf and fruit are largely composed of water, and a dry-eating Cucumber is not worth having.

Tomatoes.—Late crops will now be ripening off. Do not apply any more stimulants, as the aim should be to arrest growth. With this end in view, give only sufficient water to keep the plants from flagging. As the fruits approach a state of ripeness, it will be advisable to pick them and place them in a warm room (the kitchen for choice) to finish off.

The Flower Garden.

Bedding Geraniums (Zonal Pelargoniums) will now be rooted and the boxes of cuttings should be moved under glass; the fruit of an early vinery or peach house suits them admirably. Be very sparing with the watering can, giving no more water than will suffice to keep the stems plump. Promptly remove any decaying foliage and if growth has set in and the leaves are crowded, thin them out a little as a preventive against damping, the only enemy to be feared.

ROYAL HORTICULTURAL SOCIETY'S GREAT AUTUMN SHOW

WILL BE HELD AT

THE HOLLAND PARK SKATING RINK

Holland Park Avenue, W.

On October 2nd, 3rd and 4th, 1923.

(Book to Holland Park or Shepherds Bush on the Central London Tube Railway.
Buses 12, 17, 32, 88, pass the Rink; 49, 49a and 11 pass within a short distance.)

A GREAT AUTUMN SHOW of FLOWERS, FRUIT and VEGETABLES, with a display of AUTUMN FOLIAGE and BERRIED PLANTS; collections of choice fruit and competitive classes for Apples, Pears and Vegetables.

Prices of Admission for Non-Fellows:—

Tuesday, October 2nd	-	Open	2 p.m. to 5 p.m.	-	10/-
			5 p.m. to 7 p.m.	-	5/-
Wednesday, October 3rd	-	„	10 a.m. to 5 p.m.	-	5/-
			5 p.m. to 7 p.m.	-	2/6
Thursday, October 4th	-	„	10 a.m. to 2 p.m.	-	2/6
			2 p.m. to 5 p.m.	-	1/- (Closes at 5 p.m.)

R.H.S. Fellows' Tickets admit Free. Particulars of Fellowship may be obtained on application to the Secretary, Royal Horticultural Society, Vincent Square, London, S.W.1

CAMPANULA HALLI (New)

*Award of Merit, R.H.S., August 8th, 1923.
F.C.C., N.E.H.S., August 22nd, 1923.*

The finest Dwarf Campanula sent out for years.

See "THE GARDEN," page 427, for illustration.

A limited number of Strong Plants of this dainty little Gem are now being distributed.

(late Nobles),

WINDLESHAM, SURREY, near Sunningdale Station.

49th Annual Sale of a Choice Assortment of Standard & Bush

NAMED RHODODENDRONS

together with a very fine Collection of

HIMALAYAN & CHINESE RHODODENDRONS

including many of the newer species. HARDY AZALEAS, Cupressus, Retinosporas, Thujas, Yews and Laurels. Black Currants, Raspberries and Loganberries. Ornamental, Evergreen and Flowering Shrubs and Trees and other Nursery Stock.

MESSRS. PROTHEROE & MORRIS

will sell by auction on the premises as above

ON TUESDAY & WEDNESDAY, OCTOBER 9th & 10th,
at 12.30 o'clock precisely each day.

On View, Catalogues of Mr. White at the Nurseries, and of the Auctioneers, 67 & 68, Cheapside, London, E.C.2.

Violas.—If sufficient stock was not secured a few weeks ago, there is still plenty of time to propagate these accommodating flowers. As I stated here previously, the best rooting medium is sifted fibrous loam, parts, clean sharp sand, 1 part. Place the rough sittings at the bottom of the boxes, or of the frame, as the case may be.

Sweet Peas. The season now being over the plants should be cleared away and the supports carefully stored ready for another season.

Herbaceous Flowers. As the stems die down these should be cut over; the more woody stems should be retained as they are useful for protecting any plants of doubtful hardiness during the winter; moreover some of them will prove useful for giving young Sweet Peas a start next season, until they are able to reach the full-size stakes.

Sweet Violets. Continue to remove all runners as soon as they appear. Run the hoe among plants which are to be left to flower in the open. Hand weed, if necessary, plants in frames, and see that they do not suffer from lack of water; ventilate the frames freely, as any coddling tends to weaken the plants and so reduce their capacity for producing good flowers.

Roses.—If it is intended to plant Roses next month (the correct season), orders should be placed now to prevent disappointment in the event of certain varieties running short. The selection of varieties must depend chiefly on individual taste, but also to some extent on the use to which they are to be put; if for bedding or massing, then reliance should be placed on such "good doers" as General McArthur, Caroline Testout, Richmond, Frau Karl Druschki, Golden Emblem, Lady Pirrie and Mme. Abel Chateau. The following half dozen are mildew-proof: Christine, Crimson Emblem, Lady Plymouth, Ophelia, Red Letter Day, and Mrs. Wemyss Quin.

CHAS. COMFORT.

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian.)

GREENHOUSE AND CONSERVATORY.

Desfontainea spinosa.—This beautiful holly-like shrub with tubular red and yellow flowers is a native of Chili, and although hardy in the West, is a fine plant for the conservatory, especially if it can be planted out, for it is not long happy under pot cultivation. It grows freely in a well-drained border, in any good loam, with the addition of a little fibrous peat. It may be propagated at this time by means of twiggv, half-ripened shoots inserted in pots containing sandy soil, standing the pots under a bell-glass in a cool greenhouse.

Crocuses for Pots.—The large, named varieties of *Crocus vernus*, grown in pots or pans are very useful for the small, unheated greenhouse. The corms should be potted up as soon as they are received, placing them fairly thick in the pots or pans. After potting, stand them outdoors at the foot of a wall and cover them with well weathered ashes until they are well rooted and showing signs of growth. At this stage they should be removed from the ashes and stood in cold frames, giving them plenty of air on all favourable occasions. A sharp outlook should be kept for mice at all times as they are very fond of the corms. There must be no attempt to force these Crocuses or they will go blind and the flowers fail to develop. They are also very suitable for growing in bowls of fibre. The many beautiful species of spring-flowering Crocuses are also very charming plants for the small unheated greenhouse. For this purpose they are best grown in small, shallow pans. They require the same cultural conditions as advised for the large garden varieties. Some of the species are scarce and expensive, but most of the following are cheap and quite readily procured. CC. alaticus, aureus, banaticus, Imperati, biflorus, Sieberi, chrysanthus, versicolor and Tommasianus. Many of the species mentioned have quite a number of varieties.

Veronica Hulseana.—This beautiful New Zealand Veronica is very effective when grown in pots for the cool conservatory. Plants that have been stood outdoors for the summer months should now be removed to a cool, airy house. This plant very much resents coddling and should be given plenty of air on all possible occasions. V. Hulseana is of a somewhat straggling habit so it should be kept neatly staked and tied. Although usually propagated by means of cuttings during the spring, it is a good plan to propagate a batch at this time, as this will give a good start for next year. The more slender twiggy shoots should be selected for cuttings, inserting them in pots containing sandy soil and standing them under a bell glass in a cool house.

Clerodendron fallax is generally given stove treatment, but it is an excellent plant for the conservatory during late summer and autumn, and has now been in flower for some two months. Where it has been grown for the conservatory a number of plants should be kept for seed, as they are by no means easily procured at present. This plant can also be readily propagated by means of cuttings and if this method is preferred a number of stock plants should be kept for this purpose, wintering them in a house with a temperature of 55° to 60°. Early in the New Year cuttings should be secured if the plants are to be grown for summer flowering. The cuttings root readily in a warm propagating case.

Clerodendron ugandense is a fine, blue-flowered species which flowers during the summer and autumn. It is seen to best advantage when planted out and is very suitable for training up a pillar or the back wall of a greenhouse. It is easily propagated at any time by means of cuttings, selecting for this purpose the more slender twiggy shoots, which root readily in a case with slight bottom heat. If rooted at this time they will make good plants for next year.

Clerodendron Thomsonæ.—Specimen plants that have done duty in the conservatory should now be kept on the dry side and wintered in a house with an intermediate temperature.

Heliotropes that have been grown outdoors in cold frames for winter flowering should now be removed to a warm, airy greenhouse. When grown in pots they require liberal feeding. They are probably seen at their best when planted out and trained up the back wall of a greenhouse, and in such positions they will live for many years and flower in great profusion. Where standards are required for next winter, the cuttings should now be inserted, potting them off singly when rooted and training up a single shoot to the required height before it is stopped. Such plants may be kept going for several years by reducing the balls during spring and repotting them in fresh compost. Large bush or pyramid plants may be treated in the same way, but if rooted at this time and grown steadily on, they make fine large plants the first year.

Royal Botanic Gardens, Kew.

J. COULT.

BOOKS

HAMPTON COURT GARDENS.

SIR ERNEST LAW is generally recognised as an authority on antiquities, and particularly upon Hampton Court Palace, but he seems somewhat out of his element when dealing with plants. The little guide now published* proves that either he has no intimate acquaintanceship with the names of plants or was singularly remiss in the reading of the proofs. On a single page (page 42) giving a list of the trees, shrubs and flowers in the "King's Privy Garden," there are forty-seven mistakes of nomenclature, besides innumerable errors of punctuation and many instances where the name given does not correspond with the one used in the "Index Kewensis." Where English names are given the "man in the street" is left in utter ignorance as to which of the two adjacent Latin names it belongs to, if either. As we have dealt with one particular page, we will use it again for instances of this fault, but they abound on other pages as well. Extract 1: "Olearia, Haesti Group.—'Sweet Bay.' *Laurus nobilis*." Extract 2: "*Potentilla fruticosa*. P., tomentosa group.—Red Thorn." *Cratægea, punicea plena*." Extract 3: "*Magnolia stellata* group. 'Spanish Broom.' *Cytisus (sic ?) præcox*." In extracts 1 and 2, leaving aside the extraordinary "spilling" of commas and full-points, it will be seen that the English name does actually apply to the botanical name following; in extract 3 neither botanical name applies! The whole effect is made more wretched by the introduction in "impossible" ways of block caps, small caps and italics, so that either we are to understand that

* "The Flower-Lover's Guide to the Gardens of Hampton Court Palace," by Sir Ernest Law, C.B.; 48 pages, illustrated. George Bell and Sons, York House, Portugal Street, W.C.2; 2s. net.

the *Berberis Wilsoni* (!) group includes *Tamarix*, *Olearia*, *Laurus*, etc., or that the *Philadelphus* species mentioned are additional to the Mock Oranges! Take these *Philadelphus* species, again. This is how it reads: "*Philadelphus, microphylla* (sic!), *LEMOINEI coronarius*" (!), so that *Philadelphus* and *microphyllus* are presumably two Mock Oranges and *coronarius* a form of a genus "*Lemoinei*."

Sir Ernest Law says in his preface "the lists of flowers here presented are necessarily, to a certain extent, tentative, to be developed and improved, it is hoped, with comments and notes, another year." It is certainly to be hoped that they will be corrected at the first opportunity.

In other respects, though it lacks inspiration, the guide is well enough. R. V. G. W.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

TREATMENT OF JAPANESE LILIES AFTER FLOWERING (F. W. H.).—After flowering, the plants should not be dried off too severely, else the bulbs will suffer. First remove the pots to a cool outside border shaded from bright sunshine and plunge them to their rims in sand, ashes or light soil. Directly the foliage is faded, remove the pots to a cold frame for the winter months. Early in spring either remove the surface soil and top-dress with good compost or repot altogether. The crown of the bulb should be about 2 ins. below the surface. Treat the small plants in a similar way.

ABOUT PERENNIALS AND ROSES (M. K., Oxon).—The *Gentians* may be moved in spring. They like a nice, sandy and peaty rooting-medium. Also it is advisable to sow seeds every year. The *Primulas* and *Auriculas* would not be injured if some old mortar rubble were mixed with the soil; in fact, the plants would benefit. The new mortar would not be in sufficient bulk to do harm. Yes, *Rose Trier* in good soil would attain to a height of 7 ft.; it is a vigorous-growing sort.

ROSE GARDEN.

THE TREATMENT OF CLIMBING ROSES (T. B.).—As the trees have made such free growth they would break freely if a number of shoots were cut hard back to within a few inches of the base. Some of the younger shoots should be left their full length. *Rose Mme. Alfred Carrière* should be treated in a similar way in October.

MISCELLANEOUS.

ABOUT ANTS, ALSO WEEDS IN WATER LILY POND (G. H. W.).—Our correspondent should use powdered borax and Santal powder, which will free the pots from ants, without injury to the plants. The only effective way to get rid of the weeds in the lily pond is to empty the latter and uproot the weeds. As the pond has been emptied twice for this purpose, it is a pity that the roots of the weeds were not removed, as the raking done would be useless, only breaking off, and ensuring the clearing off, the top portion.

TO REMOVE WORMS FROM LAWNS (H. W.).—Dissolve half an ounce of corrosive sublimate (bichloride of mercury) in 15 gallons of water and apply to the lawn through a rosed watering-can. Care should be taken to sweep up the worms, otherwise fowls or other birds or animals eating them would be poisoned. Water lightly the first time, then give another light application in the course of a few minutes. A peck of quicklime dissolved in 25 gallons of water, allowed to settle and used in a clear state, will answer too. The remedy our correspondent refers to is drastic but costly.

TREATMENT OF SOIL FOR ROSES AND FRUIT TREES (R. M. A.).—As rotted manure cannot be obtained, the ground should be deeply dug and the soil thoroughly broken up. For the *Tulips* use freely Wakeley's Hop Manure and leaf-mould; these can be obtained from local sources—nurserymen, etc. The same humus-containing ingredients and good turfy loam in which the grass has perished will answer for the *Pelargoniums* (*Geraniums*). For the *Roses* dig in half a pound of basic slag per square yard, and surface dress in the winter with half that quantity per square yard. Do not use artificial manures in the case of newly planted fruit trees. Add basic slag to the soil and top-dress in winter as stated above. In the spring, surface dress with 3 oz. of superphosphate of lime per square yard. Always surface mulch on poor soil. The hop manure and any decayed garden refuse would answer in your case.

FOR BEDS! FOR EVERYWHERE!

Also Fruit Trees, Shrubs, Ornamental Trees.

Please state your wants.

H. MERRYWEATHER & SONS, LTD.
Garden Specialists, SOUTHWELL, NOTTS.**BARR'S Beautiful New Seedling NERINES**

The most beautiful and easiest grown of Autumn-flowering Bulbs for the Greenhouse.

For autumn decoration in the greenhouse few plants can compare with Nerines for their brilliant and attractive colours. The flowers, produced in umbels of 6 to 24 blooms, are borne on stout stems from 1 to 2 feet high. The colours range from dark red, vivid crimson, cerise and scarlet to salmon, coral-rose, pink, blush and white, many having a glistening lustre which in sunlight gives them the appearance of being dusted with gold or silver. They remain decorative for many weeks, and their beauty may be enjoyed in a sitting-room as well as the greenhouse, if the pots are kept in a sunny window.

12 in 12 beautiful named varieties	..	42/-, 50/-, 63/- and 84/-
6 in 6	..	18/-, 24/-, 30/- and 42/-
Mixed Hybrid Nerines (un-named)	..	per doz. 25/-; each 2/6

HEREFORD.

*Notes from Maidstone.***CHERRIES.**

It is not generally recognised
that the colder garden walls
will grow the Sweet Cherries
as well as the universal
Morello. We should recom-
mend Governor Wood,
Bigarreaus Kentish and
Napoleon, and in the Black
Cherries, Early Rivers,
Schrecken Bigarreau,
Waterloo and Tradescant's
Heart, a selection which
covers the whole range of
the Cherry season. We can
supply good Fan Trained
Trees of these at 15 - each,
or smaller at 10 6.

Established 1796.

No. 2707.—VOL. LXXXVII.]

[OCTOBER 6, 1923.]

THE TORCH LILIES

THE Torch Lilies, or Flame Flowers as they are sometimes called, are among the most handsome and striking of summer and autumn flowering plants. The genus *Kniphofia* is an extensive one, consisting of over fifty species, the majority being found in South Africa, with a few members extending into Central Africa and Abyssinia. The various species differ to a considerable extent, from the grassy-leaved *K. breviflora* with narrow leaves and slender stems about 2ft. high to the handsome and broad-leaved forms of *K. aloides*, some of which have stems up to 8ft. high. In addition to the wild species there are numerous seedling varieties which have been raised in recent years, and which, as well as being of robust growth, are a great improvement on the older kinds. The majority lose all their foliage and die down in the winter, some exceptions being *K. caulescens* and *K. Tysoni*, which form stout stems 1ft. or more high crowned with a tuft of evergreen foliage. In spite of their evergreen character these two are quite hardy, but have less handsome heads of flowers than many of the other species.

The numerous forms of *K. aloides* lend themselves admirably for planting in large irregular groups in open sunny spots or on the borders of ponds or streams. Here they provide a brilliant effect during the late summer and autumn, and once established in a deep, well drained loamy soil they require little attention beyond a top-dressing of rich soil or well rotted manure occasionally. When in full flower a large mass of Torch Lilies is very effective both near at hand and from a distance, so that these plants are of great value for grouping on lawns, in the open woodland, and on banks near water. The larger-growing kinds, including all the numerous forms and hybrids of *K. aloides*, are well adapted for associating with such plants as Bamboos, Pampas Grass and similar things, for a suitable background much enhances their beauty. All the hardy kinds are readily increased by means of division in the spring, as well as by seed, which is freely

produced in favourable seasons. They all grow well in a deep loamy soil of a rich nature, but thoroughly well drained. Anything in the way of stagnant moisture is fatal to their well being. Unfortunately, some kinds are liable to injury by frost during severe winters, and consequently should have a good covering of ashes or dry leaves to protect the crowns from harm.

Somewhere about thirty species have been or are at present in cultivation, some of the best of which are given below:

K. ALOIDES.—This, which is called *Tritoma*

Uvaria in many gardens, is one of the oldest species in cultivation, as well as one of the most handsome. It is an excellent border plant, and will flourish in any good soil, coming into flower in late summer and lasting in perfection for several weeks. One of the finest forms of this species is the variety *nobilis*, a robust and noble plant, with stems reaching a height of from 6ft. to 8ft., and bearing long heads of flowers varying in colour from scarlet to orange red. It blooms throughout the month of August. Other forms are variety *grandiflora*, with rich orange scarlet and yellow flowers in July; and variety *Saundersii*, a very free-flowering and beautiful sort with rich coral red flowers in September. Other handsome garden forms vary in colour from pale yellow to orange and red. The species is native to South Africa.

K. BREVIFLORA.—This is a dwarf kind from the Orange River Colony with tufts of grass-like foliage and slender stems about 2ft. high. They bear spikes of short yellow flowers closely clustered together from July to October. This species has been crossed with *K. Macowani*, resulting in two distinct forms, one having red flowers much like those of *Macowani*, while the other has spikes of rich yellow flowers each 1in. long. The yellow kind has been named *K. × Irvingii* and makes a good garden plant.

K. BURCHELII is closely allied to *K. aloides*, with large heads of flowers, red at the top and yellow below.

K. CAULESCENS.—This much resembles a *Yucca* in growth, with stout stems and broad glaucous leaves with a slight keel. The red and yellow flowers are produced in July in dense heads about 6ins. in length. It has been grown in gardens since the year 1862, and is one of the best known.

K. CHRYSANTHA.—A robust plant growing 5ft. high, this has heads of canary yellow flowers in August and September.

K. COMOSA.—A native of Abyssinia, this is one of the species that requires protection during the winter. It has flower-heads 4ins. long and 2½ins. broad of rich yellow flowers, from

THE REMARKABLE INFLORESCENCE OF *KNIPHOFIA ERECTA*.

K. robusta.—A very attractive appearance, but the flowers are small and trailing, and the plant is not of great height, from 4 ft. to 5 ft. The principal spikes of this species are very long, and the secondary spike often spreading below the main one. It lasts in flower from August to October. *K. Lechtman* is very like this species, but has more cylindrical spikes. In both species the upper flowers open first.

K. coccinea.—This is a hybrid between *K. Macowani* and *K. alodes*, about 2 ft. tall, with brilliant scarlet flowers, shading to orange in September.

K. densiflora.—A strong-growing species with glaucous foliage of a stiff nature and stout stems 3 ft. high, bearing dense heads of yellow flowers, the upper being tinged with red.

K. trixera.—This is a remarkable plant of garden origin in which all the flowers in time assume an erect position on the spike. The flowers are orange-scarlet in colour, and last in good condition for a long time. It is an excellent tree-flowering plant.

K. foliosa (syn. *K. Quartiniana*).—A native of Abyssinia, this does best against a warm south wall. It has long leaves and stems 4 ft. to 5 ft. high, bearing dense cylindrical heads of yellow flowers sometimes tinged with red in autumn.

K. Macowani.—A dwarf tree-flowering plant with grassy foliage and stems 2 ft. high, with richly tinted orange-scarlet flowers in July and August. It is a native of South Africa and one of the best of the dwarf kinds.

K. modesta.—A native of Natal, this charming species requires the protection of a warm south wall. It has long grassy leaves, and long spikes of white flowers in September and October. This plant has improved under cultivation, being much more floriferous than in its wild state with longer heads of flowers.

K. multiflora.—When first introduced into this country some twenty years ago this interesting and distinct species was treated as a cool greenhouse plant, which treatment was justified owing to its not flowering till the middle of November, a time of the year when few plants look happy in bloom outside. It has, however, proved quite hardy and flowered well outside in mild seasons. The stems reach a height of 6 ft. and bear a long spike of yellowish white flowers. Its home is in the swamps on the summit of the Drakensburg range of mountains in Natal. It is more of a plant for the warmer parts of the country.

K. natalensis.—A very variable plant from Natal with stiff, green leaves and flower stems up to 3 ft. high in summer. The flowers vary from coral red to yellow and are borne on long spikes.

K. Nelsoni.—In the way of *K. Macowani*, but much taller, often reaching a height of 4 ft. The 1½ in. long coral red flowers are borne on spikes up to a foot in length. It is a very elegant plant, quite hardy and easily grown. A native of the Orange River Colony, it flowers in August and September.

K. Noronhai.—One of the caulescent group, with evergreen glaucous leaves on short thick stems. The leaves are very broad and have no colour on the underside. The flowers are borne on long spikes up to 4 ft. in length, the upper ones being white, the lower ones yellow. This handsome species was introduced from South Africa in 1875. It is hardy very freely, and the tree plant is covered with it.

K. laurifolia.—This species from Natal has very grassy leaves and a flowered, one-sided spike of coral red flowers in July.

K. pectinosa.—A dwarf tree-flowering South African species near *K. alodes*, which has been in cultivation since 1874. The flowers

THE YUCCA-LIKE KNIPHOFIA TYSONI.

ONE OF THE EARLIEST FLOWERING, KNIPHOFIA RUFA

THE QUAIN YELLOW-FLOWERED KNIPHOFIA COMOSA.

are orange red, becoming yellow with age and are borne on densely crowded spikes in May.

K. ROOPERI.—Also like the above in habit, with red and yellow flowers in November. South Africa.

K. RUFA.—One of the earliest species to flower, this is a slender-growing plant with grassy foliage and flower-stems 3ft. high. The spike is lax, with yellow flowers below and red tinged ones above. It is one of Max Leichtlin's introductions from Natal, and has been freely used for crossing. Several elegant garden forms are in cultivation.

K. SNOWDENI.—This is a new species from Mount Elgon in Uganda. It was there found by Mr. Snowden, after whom it was named, growing in short grass and bush at about 9,000ft. elevation. The leaves are slightly glaucous, about 3ft. long, while the stout stems reach a height of 6ft. In colour the curved pubescent flowers, 1½ins. long, vary from yellow to red, some spikes being all

red, others all yellow. The flower-spikes are lax in comparison with many other species, and are produced in October. It has proved hardy so far, but it has not yet been tested in a severe winter.

K. TUCKER.—This is a comparatively new species to cultivation, having been introduced just before the end of the last century. It is a native of Cape Colony, at about 4,000ft. above sea-level, and was found by Mr. Tuck, after whom it was named. Of tufted habit, the leaves are stiff and tapering, while the stout flower-stems reach a height of nearly 5ft. Borne in a dense spike in May, the flowers are red at first, changing to yellow with age. It is quite hardy and more or less caulescent.

K. TYSONI.—Very close in habit to the above, with the same coloured flowers, which are, however, produced in September and October instead of May. The glaucous leaves also have a more distinct keel than *K. caulescens*, which it also much resembles in its caulescent habit and foliage.

K. TRICOLOR MAJOR.—This is a garden hybrid, probably of *K. Tysoni* and one of the *abouides* group. It is of robust habit, with glaucous leaves and stout spikes of flowers which vary in colour from dull red at the top to pale greenish yellow at the bottom of the spike. It flowers in September and October.

As the Torch Lilies are deep-rooting plants, the ground should be trenched to a depth of 2ft. or 3ft. before they are planted, and if at all heavy or wet a good layer of broken bricks should be placed at the bottom. In planting, the crowns should be 4ins. below the surface, and all the fleshy roots should be spread out horizontally, and not straight down in a bunch. The best time for replanting *Kniphofias* is in the spring, just before they start into growth. They will then make good growth during the same season, but will not flower very freely till well established. W. L.

TRIAL OF DAHLIAS AT WISLEY

THE Annual Trial of Dahlias in the gardens of the Royal Horticultural Society at Wisley, instituted a few years ago as a result of the operations of the Joint Floral Committee composed of members of that Society and the National Dahlia Society, is now producing most excellent results.

The chief object of these annual trials is to determine the fitness of the selected varieties for garden embellishment. The Joint Floral Committee meet on several occasions each year during the flowering season at the Royal Horticultural Society's Hall, Vincent Square, and from among the large number of novelties submitted for its adjudication, varieties of promise are selected for trial at Wisley the following year.

Prior to the institution of these annual trials, it was customary for awards of merit to be made to new varieties, and their value was determined solely by the character and quality of the flowers exhibited. Many beautiful varieties received awards in this way and raisers were only too pleased to record in their catalogues that such sorts had received an award of merit or some other recognition. It was quite impossible when adjudicating upon novelties submitted in this manner to determine the usefulness or otherwise of the different varieties. Habit, constitution and other essential factors were practically ignored, and it was only after the trial of such varieties in the gardens of those who purchased and grew the plants, that their real value in the garden could be ascertained. This state of affairs was considered by many growers to be most unsatisfactory. Complaints were rife that many varieties which had gained some coveted distinction were not in the least suited for garden embellishment; they were useful only for exhibition purposes. The large, handsome flowers of exhibition varieties were often found hidden away among the foliage of the plants and in consequence such varieties had no attraction for the garden lover. Not seldom, too, the flowers of novelties were placed before the joint committee arranged on wire or other supports and in this way their weak stems were not disclosed. Fortunately, all this is now changed and no variety is adjudicated upon unless it is submitted to the Joint Floral Committee without any artificial support.

During the last two or three seasons quite a large number of novelties have been placed before the Joint Committee, and the majority of these have been represented by flowers, borne on stout, or wiry, straight flower-stalks which hold the flowers well up, so that their real beauty is seen at a glance.

A Dahlia with an erect flower-stalk is a great desideratum, but even this factor in a flower does not necessarily prove the variety to be a real acquisition in the garden. Only by testing the

DAHLIA DORKING STAR, SILVERY MAUVE AND CRIMSON.

plants in a well organised trial can their real worth in the garden be determined, and such a trial the Royal Horticultural Society annually imposes upon itself, in order to test the worth of the new varieties which the Joint Committee has selected for trial from among the very large number of novelties that are each year submitted to it. Hitherto only a very few of the attractive Cactus-flowered varieties have been sent for trial at Wisley, but it is understood that all the varieties selected by the Joint Committee will in future be grown in the trial of the succeeding year.

Much credit is due to those responsible for carrying out these trials of Dahlias at Wisley. Anyone who is privileged carefully to inspect the work of the garden staff in this connexion must acknowledge how well the task is done. The trial of the present season is exceptionally satisfactory and Dahlia growers are indebted to the director of the garden and to those working under his

authority for the splendid results achieved. The trial was visited by the Joint Dahlia Committee on September 12 last, on which occasion the plants generally, were flowering in profusion and gave convincing proof of their garden value in early autumn. The warmer tones of colour appeared to predominate and in the autumn sun they were highly attractive and very showy. Only in the very few instances were the plants really unduly tall; in most cases they were from 3ft. or rather less, to about 5ft. in height and the character of their growth was generally sturdy and branching. At intervals in the rows of plants there were planted standard sorts of other season's selection. This enabled comparison to be made with the results previously obtained and this was a distinct advantage. It is customary in these trials of Dahlias to plant out three plants of each variety in triangular form, thus in this way it was possible to see and appreciate the points of the varieties quite satisfactorily. A fact which struck most of the visitors was the advance that each successive season appears to bring. Not only were the plants flowering most profusely, but in the majority of cases the flowers stood out well above the foliage on long, strong stems, proving that these flowers are ideal for use as cut flower.

Almost every type of the Dahlia is to be seen in this trial. The large-flowered Decorative, large Pæony-flowered and the small-flowered examples of the same types predominate; Mignon, Garden Singles, Star and Pompon types of the flower are each represented by the newer varieties and a few other standard sorts at present in cultivation. Altogether sixteen varieties received an award of merit and seven varieties were highly commended. No one can charge the Joint Committee with being over generous; a high standard was adopted and so long as this is maintained, the best interests of Dahlia growers will be served, provided growers give credence to the adjudications of the Joint Committee, as determined by the awards that it makes.

A brief note on some of the varieties to which awards were made may not be out of place. An exhibition single sort that received an award of merit is Mamie, maroon and rose, of good form; the well known Mignon Single, Coltness Gem, rich crimson, very dwarf, also received an award of merit. A similar award was made to each of the undermentioned varieties. Miniature Pæony-flowered: Peach, delicate rose suffusing to a cream base; Mac, very free, salmon pink, height 5ft.; Denys, a rich scarlet-crimson, and Crimson Glow, rich deep crimson. Miniature

Decorative Cactus, and a fine little Kade copper cactus, a cactus like form, in stems. Type, brilliant scarlet, very free and constant; the same, with deep crimson, very free. Jeweller, small flower with shell-like petals of soft pink colour. A few of the large-flowered kinds were seen. Peony-flowered, glowing scarlet; Jhr. v. E. Van Fets, a garden Cactus of fine form, on erect stems, pure white. Wake Up, a beautiful bicolor, cream and white. A charming white small flowered Cactus, named Snowdrift, is highly decorative, not unlike Chrysanthemum White. O. J. Quintus, Gattin Star, Dorking Star and Crimson Star were each recipients of honours, the first mentioned gained an award of merit and the other two sorts were highly commended. The pretty little Pompon variety Glow, of a pale coral colour, also gained an award of merit. Garden

Singles are splendid for the garden, a variety named E. Graham Bird, colour brilliant scarlet, is especially noteworthy and obtained an award of merit, and Nanno is another highly decorative variety of the same type; the latter was highly commended. The list concludes with a dainty variety of the Miniature Peony-flowered type named Leonie Cobb, a mauve-pink sort, and Leonie, a bright carmine flower shading at the tips to rose and of the same type.

The varieties enumerated above, having been selected for awards from among the large number of plants sent for trial, may be regarded as the best sorts of the past season's introduction. The prospects for next season are promising, as the Joint Committee has already selected for trial quite a good number of novel and beautiful varieties.

D. B. CRANE.

late and open pink or rosy pink flowers several together at end of the shoots in May.

R. campyloogynum is a dwarf bushy evergreen up to about 1 ft. high, with leathery leaves $\frac{1}{2}$ in. to 1 in. long and half as wide. The purplish violet flowers are bell-shaped, averaging about 1 in. long, borne two or three together at the ends of the shoots. A native of Yunnan and Tibet, it was first discovered by the Abbé Delavay, but for its introduction we are indebted to Mr. G. Forrest, who collected seeds at varying elevations from 11,000 ft. to 16,000 ft. in 1904 and 1906.

R. CEPHALANTHUM is said to grow up to 5 ft. in height, but our plants at present suggest a very much less pretentious shrub. The collectors describe it as growing in exposed positions at 10,000 ft. to 11,000 ft. elevation. Coupled with the fact that the Edinburgh plants flowered before those in Cornwall, this gives us the suggestion that this is a *Rhododendron* for the rock garden. The leaves are up to 1 in. long and half as wide; the white flowers are clustered six to ten or more together at the ends of the shoots. It is a native of Szechuen and Yunnan, and was first found by the Abbé Delavay in 1884, later by Mr. G. Forrest in 1909 and 1913-14, and by Mr. E. H. Wilson in 1908.

R. CHRYSÆUM may be described as a dwarf

DWARF RHODODENDRONS FOR THE ROCK GARDEN

UNTIL the last two decades the culture of *Rhododendrons* in the rock and alpine garden was mostly confined to several species and varieties from the Alps. These are of somewhat similar habit, and do not provide much scope for the embellishment of a rock garden. To-day, the enthusiast is very well supplied with a variety of plants differing in habit, leaf and flower, the season of flowering and favourable position for planting. While a number thrive in open, sunny positions, others are partial to some shelter from the midday sun. This may be largely due to the cooler conditions and more plentiful moisture thus afforded. These alpine *Rhododendrons* like plenty of rock or stone in the soil, which affords a source of moisture for the fine roots.

A very important consideration with the dwarf-growing *Rhododendrons* is their value and suitability for small gardens. The habit of growth permits of a large number being cultivated successfully in a small area and, what is equally important, most of them thrive in the varying shelter which is inevitable in many gardens restricted for space.

Most of the dwarf *Rhododendrons* can be propagated by cuttings in a cold frame, or under hand-lights and cloches at the foot of a west wall. Use very sandy soil as a rooting medium. Seeds also in numerous instances are available. The dwarf spreading habit of most rock-garden *Rhododendrons* makes their increase by layering very simple, a mulch of leaf-mould and coarse sand being frequently all that is needed. Even if not required elsewhere, it is quite worth while layering the outside shoots. There are many more roots to supply nourishment, and should anything happen to the parent plant the surrounding offspring will be self-supporting.

In the matter of soil the important point is that it must contain very little, if any, lime for the majority of *Rhododendrons*. A very good mixture would be equal parts of peat, leaf-mould, coarse sand and lime-free loam. In selecting stations for planting, avoid those which readily dry up. We read of the dwarf *Rhododendrons* thriving in open pasture and exposed ledges on the hill-sides, but in such places there must be a supply of moisture for the fine *Rhododendron* roots. Mulching is a most important item in the culture of *Rhododendrons*. This may take the form of flaky leaf-mould or spent manure and leaves from an old hot-bed; anything, in fact, to keep the surface moist and provide a little nourishment for the plants.

For reference it will be easiest to describe the species in alphabetical order, referring in more

THE LILAC-FLOWERED RHODODENDRON INTRICATUM.

detail to the most useful to select when only a few can be accommodated.

R. CALOSTROTUM is one of the late Mr. Reginald Farrer's introductions. It is his No. 1045, described as a dwarf shrub on high open alpine pasture at 12,000 ft. to 13,000 ft. It has small, scaly

form of the now very well known *R. flavidum*. It was collected on the Tibeto-Yunnan frontier at 13,000 ft. to 15,000 ft. elevation by Mr. Kingdon Ward in 1912 and again in 1913. The primrose-yellow flowers open in May a little later than those of *R. flavidum*.

R. EUCROUM is a dwarf spreading shrub described by Mr. Kingdon Ward as 1½ ft. to 2 ft. high growing in damp shady positions among Bamboos in Upper Burma at 10,000 ft. elevation. For a dwarf *Rhododendron* it has quite large leathery leaves up to 3 ins. long, with a lax cluster of three to five brick-red flowers. Coming from that district and in shade, this is a *Rhododendron* which we must protect with bracken or a cloche in winter and early spring in addition to giving it the coolest available position.

R. FERRUGINEUM, the Rose des Alpes or Alpen Rose, was first introduced in 1752. Wild plants cover thousands of acres on the higher European Alps, providing a gorgeous display of colour in June and July. Though ultimately 3 ft. to 4½ ft. high, the plants are slow in growth and are many years old before attaining this size. Wedged between the boulders in the rock garden the dwarf spreading evergreen shrubs in happy surroundings form dense masses of growths. The typical form has rosy scarlet or deep rose blossoms. There are quite a number of varieties, the name usually indicating the difference from the type, thus *album*, white; *atro sanguineum*, deep scarlet; *myrtifolium*, with smaller leaves; *variegatum*, the edge of the leaf creamy white; and *major*, with larger foliage and flowers.

R. FLAVIDUM and *R. PRIMULIUM* are now regarded by most botanists as synonymous. The plants form sturdy little evergreen bushes up to about 2 ft. high with small, scaly leaves ½ in. to 1 in. long. In April and often again in autumn the plants produce freely the primrose-yellow blossoms from which the name is derived. Mr. E. H. Wilson first introduced this charming *Rhododendron* from Western Szechuen in 1905. Give it a place facing west and nicely sheltered in case of late spring frosts and wind during the flowering period.

R. HALENSE is a hybrid between *R. ferrugineum* and *R. hirsutum* and, in common with many hybrids, is more free in growth and generally amenable to garden culture than either parent. Hence it is not only a good rock garden evergreen, but a valuable front row plant to group along the front of a shrubbery, giving masses of deep rose-coloured flowers. It is readily increased by cuttings.

R. HIRSUTUM is the hairy form of the Rose des Alpes. It is also a native of the European Alps but is found on limestone formation, hence, other conditions being suitable, *R. hirsutum* should thrive in rock gardens built with any stone. As a matter of fact, it is not so often seen in good condition under cultivation as is *R. ferrugineum* and varieties. Do not, however, let me discourage the planter, as in happy surroundings it is a charming rock garden shrub.

R. HYPOLEPIDOTUM forms a dwarf spreading evergreen bush 2 ft. to 4 ft. high with scaly aromatic leaves up to 1½ ins. long. Seeds collected by Mr. G. Forrest on the Mekong-Salwin divide at 11,000 ft. to 13,000 ft. germinated very freely. The small open yellow flowers are of quite a dainty nature, the plant being very pretty when flowering freely.

R. IMPEDITUM I should place first on the list of dwarf *Rhododendrons* for the rock and alpine garden. It is also valuable for small beds and massing in the pleasure grounds under similar conditions to that afforded the dwarf *Ericas* and *Callunas*. *R. impeditum* is quite as easy to cultivate, being readily and freely raised from seeds, cuttings and layers, thriving in similar soils and positions. The plant is a native of Western China and was first introduced by Mr. G. Forrest in 1911. Within eighteen months of sowing the seeds, some of the small plants, though out of season, were producing the first violet

purple or lilac-purple blossoms. The plant was first named *R. fastigiatum*, and plants are still grown under this name, but the latter differs from the species under consideration in the grey hoary appearance of the leaves and the lepidote corolla outside, that of *R. impeditum* being eplidote. A dwarf evergreen, growing in low, dense tufts up to 1 ft. or more in height and correspondingly wider, the dainty blossoms are freely produced in late April and May. The seedlings vary in colour from pale mauve to deep violet-purple.

R. INTRICATUM was the first of the dainty dwarf mauve or lilac coloured *Rhododendrons* introduced from China. It was introduced by Mr. E. H. Wilson from Szechuen in Western China when collecting on behalf of Messrs. Veitch in 1904. Growing at 11,000 ft. to 15,000 ft. elevation, it is quite hardy, but as the flowers are produced in April, they are liable to damage by spring frosts. Hence, spots sheltered from the morning sun should be utilised when selecting the planting site. In addition to the season of flowering several botanical differences readily separate *R. intricatum* and *R. impeditum*, the one we usually investigate being the long protruding stamens which mark *R. impeditum*. In *R. intricatum* the stamens are short and set in the corolla tube.

R. KAMTSCHATICUM is one of the most remarkable and distinct *Rhododendrons*. It is a low-growing deciduous shrub a few inches high, increasing by means of thick fleshy roots spreading underground and producing suckers. It is a moisture-loving species, and our best success with the plant has been by placing the bottom part of a hand-light over it and mulching with sphagnum moss which is kept moist in dry weather. The rosy crimson flowers usually produced solitarily, but sometimes in pairs, open in June. It is a native of North-East Asia, and though first introduced in 1799, is still rare.

R. LEPIDOTUM is a native of Nepal and Sikkim, and more recently Mr. G. Forrest found plants on the Tali and Lichiang Ranges at 8,000 ft. to 11,000 ft. elevation. We have perhaps grown the Himalayan plant more because of its very distinct characters than for its floral beauty. Mr. Forrest's description of the Chinese form as a dwarf shrub 6 ins. to 10 ins. high with rich crimson-rose flowers suggests that this will prove a superior garden plant if hardy enough for general cultivation.

R. PROSTRATUM, as the name suggests, is a spreading shrublet introduced by Mr. G. Forrest. He found it at varying elevations between 11,000 ft. and 16,000 ft. on the Lichiang Range in 1906 and 1910, also on the Tali Range, North-West Yunnan, in 1912-13. It appeals to me as the most desirable and choicest of all the dwarf species. Picture a dwarf plant with broadly funnel-shaped flowers, rich crimson in colour, often solitary, but, again, sometimes in pairs. This is certainly one of Mr. Forrest's most striking introductions.

R. RUPICOLUM is another species introduced by Mr. Forrest. He collected it in the Lichiang Range in 1910 at 14,000 ft. elevation. It is a dwarf, much branched shrub, its most notable characteristic being the broadly funnel-shaped flowers, which are deep rich plum-purple in colour.

R. SARGENTIANUM is a much branched, compact shrub 6 ins. to 1 ft. in height, more, no doubt, when old. The leaves average only ½ in. long, the small pale yellow flowers clustering six to eight or more together at the ends of the shoots. Mr. Wilson introduced the plant from Western Szechuen, collecting it during 1903, 1904 and 1908.

R. SCINTILLANS is one of the lavender or purple-blue flowered species, taller in growth than either *R. intricatum* or *R. impeditum*. The plant forms a much branched twiggy shrub of free

growth up to 2 ft. or more in height. It has rich purple-blue flowers with long stalked styles and stamens.

R. WILLIAMIANUM is said to grow up to 5 ft. high as a wild plant, but with us it is a dwarf shrub of spreading habit less than 6 ins. high. In Cornwall I saw plants approaching 1 ft. high. It has leathery rounded leaves ½ in. to 1 ins. long and broad. The rose-coloured flowers are bell-shaped 1 in. to 1½ ins. long and broad, borne two or three, rarely more, together at the ends of the shoots. One of the daintiest species of the genus, the plant thrives best when given a position affording some shade and moisture, also, as young growth starts rather early, protection from spring frosts. With a mulching of leaf-mould the branches spread freely and root readily, providing an easy means of increase. A. O.

THE BREAKING OF TULIPS

EVER since the International Potato Conference of 1921, when the experts were all agreed that such diseases as mosaic, curl and leaf-roll are conveyed from plant to plant by sucking insects, such as green flies, I have felt inclined to believe that the breaking of Tulips is a disease which is communicated to healthy bulbs by the insects which settle on them, especially when they are out of the ground in the summer. Within the last year I have suggested this explanation to more than one scientist, but I am not sure that anyone has yet set out to prove or disprove it. It has been a matter of great regret to me that I have now no time to carry out research work of this kind, but I hope it will be taken up.

My impression is that it is not a green fly that is the cause of the mischief, but rather a white or grey fly which settles on the bulbs after they are lifted and stored and which then multiplies rapidly. In the last fifteen years I have lifted many thousands of Tulip bulbs with my own hands, and I never remember finding flies already settled on them. They have always appeared some weeks later when the bulbs were lying on open trays in my bulb-shed. For the last few years I have tried to store all my Tulips in paper bags as soon as they have dried and been cleaned and, when I have done this, they seem to escape attack by the insects.

One curious fact is that wild species of Tulip seem much less liable to break than garden hybrids. It may be that the skins of the wild species are much harder and more persistent than those of the hybrids, which are thin and apt to peel off and leave the naked bulbs exposed. The insects are therefore attracted rather to the hybrids than to the species.

Even if this explanation is ultimately proved to be correct, and even if we discover what is the particular form of infection conveyed from bulb to bulb by the flies, it hardly likely, as Mr. Jacob seems to suppose (*THE GARDEN*, September 22, page 487), that we shall be able to ensure that diseased or broken bulbs are always equally sick or disfigured to the same extent. Annie McGregor will still be fickle, and vary from year to year just as every invalid has his good and bad days. It may be possible to prevent *Marksmen* or *Scarlet Emperor* from producing striped flowers of scarlet and yellow by keeping the bulbs protected from attack by the flies, but once they succumb to an attack no one can foretell the extent to which the disease will disfigure the flowers.

What a cruel and unjust imposition that will kill the disease in the bulbs, for no bulb seems able to recover unaided. The disease is seldom fatal and is chronic.

Anyone who sets out to raise Tulips from seed must have patience, for it will be five years at least before he sees a flower. A Tulip is, unfortunately, one of those bulbs which send out a crop of root fibres in the autumn and no fresh crop during that growing season. An Onion, for instance, and the corn of a *Gladiolus* stem, however capable of making almost continuous growth,

and a *Gladiolus* seed sown under glass early in the year will produce a flowering plant by the early autumn. Seedling Tulips refuse to allow themselves to be hurried. They are, I think, much more manageable in pots than in the open ground for the first two years of their existence, even if their objectionable habit of making droppers leads eventually to some confusion and to the appearance of examples of the same Tulip in several parts of the seedling-bed. My own practice has always been to leave the pots plunged to the rim in the open until the young plants shew through

and in the spring. That is the time when the protection of a frame or of an unheated house is most valuable, for the foliage is able to develop and ripen instead of being cut off by unseasonable weather.

When the seedlings come at last into full flower in their seventh year, the reward is great. They are an amazingly interesting study, and the more one studies them the more difficult it often is to decide to destroy any one of them. Few seedling Tulips are frankly ugly.

W. R. DYKES.

MORE ABOUT THE GREAT AUTUMN ROSE SHOW

(Continued from page 503)

IN the open class for a smaller, but still large, collection the judges also felt constrained to award extra prizes, and even then some really good efforts were unrewarded. Mr. George Prince was first with a superb group, including Los Angeles, Souvenir de Claudius Pernet and Mrs. George Sawyer. Mr. Walter Easlea, who was second, gave especial prominence to Melody, James Walley, Hoosier Beauty and Mrs. Henry Morse. Mr. F. G. Edwards was third.

The class for thirty-six varieties of miscellaneous Roses was cancelled, but there very many exhibits of eighteen varieties, and here Messrs. A. Warner and Son were first with excellent vases of Padre, Golden Ophelia, C. V. Haworth and Independence Day. Mr. F. Spooner, who was second, included

Golden Emblem, Golden Ophelia, Severine and Ophelia. Messrs. J. Jeffries and Son were third.

In the first prize collection of twenty-four varieties of decorative Roses were to be found the most deliciously fragrant Roses in the Show. These were a vase of Mr. George Lilley's Marcia Standhope, a pure white variety said to be a seedling from Frau Karl Druschka, though its appearance does not suggest that parentage. It is quite distinct in shape and not so rampant in habit, yet very free-flowering. Mr. Lilley also shewed his new pink variety Mrs. E. J. Hudson. Mr. J. Mattock was second with excellent vases of Lady Pirie, Padre and Hadley.

As usual, the baskets of Roses were numerous and exceedingly beautiful. The best three of

exhibition Roses were those of J. G. Glassford, Marjorie Bulkeley and W. E. Wallace, shewn by Messrs. Hugh Dickson, Limited. Mr. C. Gregory was a good second. Messrs. Alex. Dickson and Sons, shewing glowing baskets of Betty Upchurch, Lady Pirie and Lady Inchquin, were first in the class for three baskets of decorative varieties. Their dwarf Polyantha Roses in baskets were also very charming examples, and here the best three were of Mrs. W. H. Cutbush, Jessie and Orleans, shewn by Messrs. Lane Brothers.

The exhibition Roses, shewn on boards, were mostly very bright and fresh, but nearly all the blooms were so overdressed that their characteristics were destroyed. In the first prize twenty-four varieties, shewn by Messrs. Hugh Dickson,

THE VERY USEFUL NEW YELLOW ROSE RICHARD E. WEST.

THE SCARLET AND BUFF ROSE MARGARET MCGREDY.

THE PRIMROSE YELLOW HYBRID MUSK ROSE AURORA.

the very best were Capt. Kilbee Stewart, H. V. Machin, Lady Alice Stanley, George Dickson and Molly Bligh. The second prize set of Messrs. D. Prior and Sons were a trifle larger, but their blooms lacked the colour of the premier exhibit. The best were George Dickson, Mrs. J. H. Welch, J. G. Glassford and Mrs. George Norwood.

In the second class, which required eighteen blooms, the quality was very high and Mr. George Prince won chief honours with a splendid collection, which included Chas. E. Shea, George Dickson, Admiration, Golden Emblem, and Martha Drew of great merit. A bloom of Gorgeous in the second prize collection of Messrs. F. Smith and Sons was certainly the best in the trade classes and well merited the silver medal which was awarded to it. Other especially good blooms were His Majesty and Augustus Hartmann.

In the trade classes the Tea and Noisette Roses were rather poor and, as was the case at the Regent's Park Show in the summer, were distinctly inferior to those shewn in the amateurs' section. Mr. George Prince had the best trade collection, while Messrs. D. Prior and Sons were second.

AMATEURS' ROSES.

Competition was particularly keen in this section, which was also responsible for many really excellent blooms. As we remarked above, the Tea and Noisette varieties outshone those staged by the trade. The first prize nine blooms, shewn by that regular and enthusiastic exhibitor, the Rev. F. R. Burnside, Great Stanbridge, reached a high standard of excellence. The varieties included Alex. Hill Gray and Mrs. Foley Hobbs. In the succeeding class the six Teas staged by Dr. Hayes, Dunster, excelled them and were of really magnificent

quality in every respect. He included perfect specimens of Mrs. E. Mawley, Maman Cochet, White Maman Cochet and W. R. Smith.

Exhibition Roses were also of great value and the classes induced strong competition. The first prize, twelve distinct varieties, were shewn by Dr. Turnbull, Colchester, who had beautiful examples of E. M. Burnett, Constance Casson and Rev. F. Page Roberts. Mr. G. Spreight, Market Harborough, was a good second and he shewed, in a magnificent example of George Dickson, the best bloom in the amateurs' section. Mr. F. H. Fieldgate, Colchester, shewing splendid blooms of such as George Dickson, Augustus Hartmann and Mrs. Charles Huster, won the first prize for nine blooms. The best six, in the class for growers of fewer than 500 plants, were

bowl of Ros. Mrs. R. D. Ruff, Sharnbrook, was a good second in the dinner-table class.

In the open section the first prize dinner-table was arranged by Mrs. Tisdall, Woodford Green, who used Melody very successfully. Miss Muriel Cant was second. The best bowl in this section was of Golden Emblem, arranged by Mr. W. R. Appleton.

THE PERIWINKLES

PLANTS of the small-leaved species, *Vinca minor*, are very widely grown in gardens. The Vincas are very accommodating plants and among the most useful, as in most gardens and pleasure grounds there are positions where neat-looking plants will not thrive, and in such places weeds soon take the lead and become a nuisance. Under such trees as Cedars, especially under the Cedar of Lebanon, it is a difficult task to induce a nice green undergrowth, but I have found no difficulty when employing *Vinca major*. The plants soon formed a dense green carpet which, speckled with the lovely blue flowers, during a part of April and throughout May and June made a charming picture. I once had occasion to carpet a quite open border—the front portion—with this variety, and the plants grew so rapidly in the mixture of soil, old lime rubble and leaf-mould that at one end, adjoining a wall, the shoots grew up the latter several feet and were then assisted by neat supports, the effect being very pleasing, as the position was one near to a door leading through the wall from a shrubbery to a walled-in garden. Propagation is quite easy. G. G.

RICH PINK AND FRAGRANT, ROSE VICTOR WADDILOVE.

THE CODLING MOTH

(*Cydia pomonella*, Linn.)

BY HERBERT W. MILES, B.Sc., Biologist, Kirtton Agricultural Institute.

DURING the heavy gales which swept over England during the latter part of August much loss occurred to growers in East Anglia as a result of windfalls. Apples and Pears fell in great numbers, and the fact that there were so many on the ground at once drew attention to

the very considerable amount of injury to the fruit by codling moth caterpillars.

Usually, "wormy" Apples fall a few at a time, and the extent of the injury and loss due to the pest is often underestimated. No definite figures are available as to the actual loss in this country, but in America it is estimated that the loss due to codling is about \$12,800,000

THE CODLING MOTH.
(Enlarged.)

YOUNG FRUITS

Showing, on the left, calyx open, indicating right stage for spraying; to the right, calyx closed, stage too late for spraying.

per annum, and a further \$3,200,000 per annum are spent in control measures, making a total of \$16,000,000, or approximately £3,000,000 sterling. In 1921 "codling" damage was reported as serious in at least sixteen different counties, and it probably occurred in many others to a less noticeable extent.

The injury caused by this pest is very well known, especially to the housewife. Brown tunnels through the flesh of the fruit, entrance and exit holes with adhering frass or excrement, partially or entirely destroyed pips, and the presence of a pinkish white, active caterpillar with a dark head either in the core or in a tunnel are characteristic and unmistakable signs of codling attack. Fruits attacked in this way fall prematurely and are very little use commercially, though they can be utilised for home consumption and are quite suitable for jelly-making.

The insect responsible for wormy Apples is the codling moth (*Cydia pomonella*, Linn.). This moth is from half to three-quarters of an inch across the fore wings, which are rather greyish and bear transverse wavy lines and streaks. The borders are slightly darker in colour and towards the tips of the wings there are brownish or golden red metallic patches. The hind wings vary slightly, but slaty grey is the usual colour. These moths are to be found on the wing at twilight in early June, soon after the fruits of the Apple have set. After mating takes place the females deposit small, rather flattened, translucent eggs about the young fruits or on the leaves and stems near them. The duration of the egg stage varies with the temperature and other climatic conditions. American observers state that they noticed the moths flitting about the plantations for a period of six weeks before any eggs were laid owing to the low temperature which continued

during that period. The eggs usually hatch in from a week to a fortnight, and the caterpillars usually make their way to the calyx end of the fruitlet, where they tunnel their way inside and feed on the flesh of the Apple or on the pips. The newly hatched caterpillar is minute and white, and has a prominent black head. Within the Apple, where growth and development take place, it gradually assumes a pinkish tint. The body is covered with scattered, whitish hairs and has sooty spots about the segments.

At maturity, when the caterpillars measure upwards of half an inch in length, they leave the fruit by means of characteristic exit holes, and may crawl to some shelter or crevice about the tree or lower themselves to a branch or to the ground by means of a silken thread. For pupation a protected site is chosen, and the grub gnaws out a cavity, spins the fragments into a cocoon with silk, and changes into the pupa state, from which, by about the middle of August, a second brood of moths emerge. These proceed to lay eggs, which give rise to the brood of caterpillars, which in this country frequently cause serious damage from towards the end of August to the middle of September. When mature these caterpillars spin up about the trees, on fencing stakes, or the supports of very young trees, and remain in this condition until the following spring. Should Apples containing caterpillars fall to the ground, the caterpillars usually ascend the trees to find sites for winter quarters.

It is important that growers fully grasp the details of the life-history of this pest, because knowledge of this is essential if control measures are to be successfully carried out.

For control of the codling moth, measures take the following forms: (1) Spraying, (2) Banding, (3) Clean Cultivation.

SPRAYING.—It is stated by American workers that some knowledge of the seasonal history of the pest, a reasonably efficient spraying outfit in good working order, a willingness to observe

and take time to be thorough in the application of the spray are the essential factors in the successful control of the codling moth. The spray to employ is lead arsenate at the rate of 4lb. of paste to 100 gallons of water, and to this should be added 5lb. of soft soap (if hard water is used more soap will be required). This spray must be applied after the fruit has set and when the calyx is still open. It is important that the spray be lodged in the calyx cup so that when the young larvæ reach it and commence feeding they are destroyed by the poison. As the fruit develops the calyx closes and retains the poison which kills any grubs endeavouring to enter the fruitlet.

Since the second brood of larvæ are likely to enter the sides of the fruit and may feed on the leaf tissue for a short while before attacking the fruit, it is obvious that another spraying is necessary. The same formula is used, and this time the entire tree is covered. The correct time at which to apply the second spray varies, and a few days may make all the difference between success and failure as regards controlling the pest. To fix definitely the time to spray, it is found that the best method is to gather a few infested Apples, cut some open, collect the caterpillars and place them with the other Apples in a small wooden box covered with a sheet of glass which fits closely so as to prevent the insects from escaping. The box should be placed where it can be observed every morning without any special effort. Inside, the caterpillars will finish their feeding, will change into pupæ, and finally the moths will emerge. The correct time to spray is indicated by the presence of moths in the box.

BANDING.—In addition to spraying, it is advisable, in cases of severe infestation, to band the trees with sacking or corrugated paper, and thus afford a readily available winter shelter. This is an old method of control and very useful for reducing the number of codling maggots. Miss Ormerod ("Manual of Injurious Insects") quotes the following from an Australian publication dated 1886: "*Banding the trees*: For this purpose old sacks, old clothes (if woollen all the better), or brown paper may be used, but the latter is not so good. These should be cut into strips about eight inches in width and of a sufficient length

APPLES ATTACKED BY CATERPILLARS OF THE CODLING MOTH.

Left, shows exit hole. Right, interior of attacked fruit, showing caterpillars and damage.

to go round the trees. Each strip should be folded in half and the folded edge again turned down, so as to make a double fold about an inch and a half wide. The band will then be about two and a half inches wide. Insert a piece of cord, or what is better, wire, in the double fold, and tie round the trunk of the tree about six inches from the ground, taking care that the folds are at the top and the second fold placed next the tree." When the larvæ have spun up in them, the bands are removed and burned with the cocoons in and about them.

CLEAN CULTIVATION.—As general measures

orchard refuse, prunings, hedge brushings and the like should be burnt. The windfalls in infested orchards should be collected and used or fed to pigs so as to prevent the caterpillars escaping. Poultry, when allowed to run in orchards, do much good by destroying caterpillars on the ground or about the lower parts of the tree trunks. Winter washing with caustic soda at the rate of 5lb. to 25 gallons of water may do some good by destroying any cocoons with which it comes in contact.

It is probable that the greatest freedom from codling moth injury will be secured by a judicious combination of the methods above indicated.

A CHOICE MEADOW RUE.

I CAN only recollect meeting *Thalictrum Chelidonium* in a nurseryman's exhibit once, and it seems exceedingly rare in private gardens. It is sure to please the most fastidious plant-lover devoted to dwarf plants. Its height is just about the maximum some of the ultra-keen growers of choice alpine would put as their standard—6ins. Then it has lovely, finely divided foliage, one of the favourite features of these Meadow Rues. From this there rise little spirelets of flowers with rosy-lilac sepals and soft yellow stamens. It is but rarely that the height of 6ins. is exceeded, but I do not know that it is a disadvantage in many places to have it a little taller, as the flowers are large for the Meadow Rues. One must speak with considerable reserve of the cultural needs of this plant from the high Himalayas. It certainly ought not to have a stiff or wet soil with us, but should succeed in a well drained one with plenty of stone in it and made rather firm. It has come so rarely into cultivation, however, that comparative experience is difficult to obtain, and each one who tries it may have to learn for himself. Some suggest practically moraine treatment with lots of water in spring, but almost perfect dryness below in winter.—S. ARNOTT.

CORRESPONDENCE

A GLADIOLUS SOCIETY?

MAY I ask you to insert a paragraph to the effect that I should like to hear from anyone interested in forming a Gladiolus Society. I think the time has come to form such a society if only for the purpose of registering and classifying the ever-increasing list of new varieties.—A. PAYNE, 135, Olive Road, E.13.

GENTIANA FARRERI.

HOW is it that we see so little in gardening papers of the beauty of this autumn-flowering Gentian? And yet I doubt if there is any Gentian in spring that equals it in colour. One reason occurs to me is that it is a plant which succeeds best in northern gardens where the moisture of the soil is more constant, and another is that it has never been shewn in full beauty of colouring at any show in Vincent Square. It is a pathetic thought that perhaps the flowery extravagances of Reginald Farrer's language in describing it has tempted gardeners to believe his description exaggerated. I am truly glad to say that *no description* can exaggerate the beauty of this flower when grown to perfection. A fortnight ago I had a bloom or two sent me from a garden in Wensleydale, which so surprised me by their beauty, size and brilliant colouring that I sent on to other horticultural friends to know if my description was correct, or if by chance it were an exceptional variety. This is my description. "A fine, bold flower, quite as large as the well known *Gentianella* of spring gardens, but with *pure* turquoise blue petals prettily reflexing. The throat *pure white* and a little deep purple shading at the entrance of the throat. The outside of the tube is prettily striped with chocolate." Could anyone desire a more lovely thing? and the best bloom remained in beauty for five days in water. The answer came, "*Your description is quite accurate.*" I know no flower of such exquisite colouring. Many people love their spring garden; this flower makes the autumnal garden still more exquisite.—EDWARD H. WOODALL.

REFERRING to A. H.'s note on *Gentiana Farreri* in your last issue, it would be interesting to know how A. H. procures ripened seed. In these parts the plant blooms from September onwards, but the seed never ripens, and we have therefore to propagate by division in the spring. Old clumps weaken and cease to bloom, they also get the "yellows." We are on the carboniferous limestone formation; perhaps the plant dislikes lime. Mine are planted in leaf-mould, but no doubt the lime gets in somehow. The weakening may be caused by poverty, for every spike seems to have a separate root and all massed together in a clump. Perhaps A. H. will be kind enough to write a further note.—H. M. N. R., Yorks.

EUCOMIS PUNCTATA AS A WINDOW PLANT.

THE genus *Eucomis*, with its five or six species, seems to get less attention from cultivators generally than its merits deserve. The plants are

EUCOMIS PUNCTATA, GROWN IN A HOUSE-WINDOW.

natives of the Cape, so they are obviously half-hardy, a fact which doubtless militates against their popularity. I have grown *E. punctata* as a cool greenhouse plant, which environment suits it admirably. It was only the other day, however, that I was strongly convinced of its suitability as a window plant, having been attracted by it in a window of a Portobello villa. I send you a photograph of the plant. Its channelled, lanceolate leaves are very attractive and when these are surmounted by a half dozen or so of its white flower spikes, slightly tinged with pale green, they complete a very pleasing picture; its culture is of the easiest and it increases rapidly by offsets.—CALEDONIA.

THE FLORIDAN LILY.

LILIAM CATESBÆI is very rarely seen in this country and though I myself have grown Lilies for many years I have never yet seen it in the "flesh." It appears that the few plants that do get to this country rapidly die out, but I am hoping in the near future to be able to distribute one or two bulbs to my Lily-loving friends. The following letter sent to me by an old and valued entomological correspondent, will, I hope, clear up some little points in the method of growing and cultivating this really fascinating Will-o'-the-Wisp.

"... Very few of the Lily seeds sent me have grown; those of last year that survive are small, averaging 2 sq. in. of foliage apiece. I do not think that Florida conditions are favourable to most Liliiums, though I have heard of successful *L. regale* in the state.

"A week ago, August 30th, I took some of my Scouts to a Scout Camp about 15 miles from this place and on a 'Nature Hike' along an abandoned railway embankment, I found a bog where *Lilium Catesbæi* was in bloom. Yesterday I made a special trip to get bulbs of it for you and found altogether 27 plants on an area of some acres. I took along a stout chisel and got up solid chunks of the earth with the plants; they grew solitary in a sort of turf of low sedges and weeds in very open pine woods (*Pinus caribæa*, very similar to the *P. maritima* of S. Europe); the soil is sand and sour leaf-mould. The 27 were all I could find. Doubtless there were seedling plants not in bloom, but it would be almost impossible to find them in the

herbage is not in flower. All that were ready to fade I brought home with pods attached and will try to raise some seed for you. The land where they grow is low and nearly level, with pools of water standing wherever there are slight depressions. I do not think this sort of land is ever dry, though water may, at times, be as much as a foot below the surface. Characteristic plants are *Platanthera* among Orchids, *Liatris* spp., small patches of *Sphagnum* and *Lycopodium*, many Sedges, Pipeworts, depauperated Saw Palmetto and ericaceous plants on the higher knolls, and bog plants in general, though the soil is firm and tough with sedge roots.

Each Lily plant had a tuft of leaves alongside the flowering bulb to replace it for next season, so

THE TEASEL.

THE points noted by the Editor last week (page 508) were present to my mind, but I think he will find that some authorities at least regard *D. Fullonum*, not as a species, but as a cultivated variety of *D. sylvestris*, the hook to the scale being induced by cultivation in rich soil. It is true that my Teasels have not the hooked scale and would not therefore be regarded favourably by fullers, but all the same they suggest the question how a fuller would use the hooked plant for his purposes. I have little skill in machinery, but I believe the flower-cone of the Teasel was split into four segments and that these were affixed somehow to a revolving cylinder, which raised the nap of the cloth to the extent and in the direction required. Authoritative information on this point would be interesting.—SOMERS.

THE JAPANESE BANANA.

THE Banana plant is not grown very much in the open in this country except in favoured places, and evidently one of those places must be Oxted. The illustration shews a good specimen of *Musa japonica* which was planted here about twenty years ago and grown under normal conditions at the foot of a bank facing south. It has attained a height of about 15ft., with leaves 6ft. long and 20ins. wide. Flowers are produced and fruit is formed, but the latter never really matures or attains any size. The plant is protected by a thatched roof in winter, but apart from that receives no other attention. *Musa japonica* is the hardiest species of Banana. Other kinds are mostly grown for greenhouse decoration. *Musa Ensete*, a native of Abyssinia, is used for summer bedding. *Musa*

MUSA JAPONICA OUTDOORS AT OXTED.

I have planted them in a couple of seed pans to mature—all but five, which I put in my *Caladium* garden where the soil looks exactly like that adhering to their roots and is nearly as wet. Apparently they seed freely so it is odd that they should be so solitary—rarely nearer than 20ft. to 50ft. apart. I am putting the seedpans in a shallow tank in my greenhouse, a little above the water level, but with *Sphagnum* underneath to give water from below and hope to mature the bulbs for you. In summer the sashes are removed from my greenhouse, and late-spring admits the summer rains, supplemented by overhead spray supplied from a nearby pond in a gasoline pump. . . ."

The spots such as my correspondent describes can be easily made in the swamp garden. The description is lucid and such as a lifelong trained field worker alone could give. I place this letter on record as an indication of the natural conditions under which this *Lilium* grows.—J. HENRY WATSON, F.E.S., *Withington, Manchester.*

Cavendishii from China and *Musa sapientum* from the Tropics are stove plants.—R. C. JOLIFFE.

LING CHANGING COLOUR?

I HAVE, on a rocky knoll in my garden, some forty Heather plants (kindly left to me by the drought of 1921, which killed as many more). When I first came here, these were all pink, so, in order to introduce some variation, I bought three white ones. I have noticed since that there were, after all, an odd white or two, and last year several more appeared. This year they are all white, with the exception of a few seedlings (of which there are a great number scattered about), and this applies not only to the ordinary wild ones but to several ericaceous and other garden varieties, the names of which, however, I do not know. The soil is very poor, has an acid reaction to litmus paper, and contains practically no lime. I would be very glad to know if above is merely a passing phase and whether there is any chance of the plants becoming pink

again, and also what is the cause of the sudden change. I should be very glad if some correspondent could enlighten me on the subject—H. LINDEY, *Windermere.*

THE OENOTHERAS

PALÉ primrose yellows, those of deeper tone, rich golden yellows and orange yellow, all are unmistakably associated with the Evening Primroses (*Oenothera*).

During a dull afternoon or evening, and when the weather is inclined to be showery, hundreds of flowers expand on quite a few established plants. These, together with the white flowers of *Nicotiana glauca*, are sufficient to attract one into the damp garden on such occasions, when otherwise one would not feel inclined to wander forth. From June to early October the *Oenotheras* never fail to flower during the latter part of every day.

For many years it was my duty to plant out nearly thirty thousand bedding plants for the embellishment of a large flower garden, and in this garden the *Oenotheras*—permanent occupants—stood out conspicuously in the midst of a profusion of blossom. Towards the latter part of the summer Lilies added their fragrance to that of the *Nicotiana* and to that also emanating from a large border filled entirely with sweet-scented foliage plants, such as scented *Geraniums*, lemon-scented *Verbena*, *Eucalyptus*, etc. The *Oenothera*, to me, personally, seems to fill a gap which cannot be adequately filled by any other flowering plant.

Ordinary specimens may be grown in quite common garden soil, but fine ones, possessing flowers of intense colour and much substance are grown when a really rich loam is used as a rooting medium. The worst position for these plants is one in a border too close to the roots of shrubs, as the annual growth is poor and the flowers puny.

I refer, of course, especially to the hardy herbaceous perennial *Oenotheras* and not to the annual and biennial ones. Old plants are difficult to transplant with success, as their fleshy roots ramble away several feet from the central stem. I have found it advisable in such cases to dig right round the plant in spring and remove all the roots beyond, approximately, 9ins. to 1ft. from the stem, then fill in the small trench with rich loam and a small quantity of leaf-soil. The following spring these plants, so treated, may be shifted without the slightest check, as many new, small roots will have taken possession of the special compost during the year. Young plants are easily transplanted, but sometimes one wishes to retain old favourites too. Both transplanting and division are best done in spring. There is one attention these plants always need, that is, the daily removal of the fading flowers during the summer months, as if left on they give to the plants a neglected appearance.

Some good varieties include *Oenothera macrocarpa*, yellow; *O. taraxacifolia*, white; *O. Fraseri*, orange yellow; *O. biennis grandiflora*, pale yellow, very fine; *O. fruticosa Fraseri*, rich golden yellow; *O. punila*, small, yellow flowers borne on a dwarf-growing plant; *O. riparia*, another dwarf-growing plant with flowers borne on short stems; *O. ovata*, dwarf, bright yellow, suitable for a rockery or similar border. Two other varieties suitable for a rockery are *O. brachycarpa*, orange yellow, and *O. eximiae*, bearing large white flowers. *O. missouriensis*, with deep yellow flowers, is suitable for planting near the edge of a raised border. GEO. GARNER

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Celery.—Continue to earth up the main crop of Celery, and bear in mind that large quantities of soil at one time are likely to cover the heart of the plant and thereby check the growth. Remove all side growths, weeds and decaying leaves, and, if the roots are dry, give them a thorough soaking of water the day previous to earthing up. Choose fine weather for the operation, and the leaves may be tied up with raffia, which will greatly facilitate the work.

Winter Salads.—In some establishments these are very important, and Lettuces in particular are eagerly sought after during the winter months. If seeds have been sown at frequent intervals, there will be no lack of plants at the present time, and a cold frame should be filled, placing the seedlings 1ft. apart and about 15ins. from the glass. Old potting compost mixed with ordinary garden soil will make a suitable rooting medium. Most gardens possess a sheltered border, and here Lettuce will succeed during an average winter. Keep them free from weeds, and use the Dutch hoe at intervals. Mustard and Cress should be sown about every fortnight and the boxes placed in a warm greenhouse. Endive, where it is appreciated, may be planted in frames, allowing 15ins. between the plants.

Winter Greens.—Owing to the dry conditions prevailing some weeks ago, these have not made such headway as in former years except where plenty of water could be afforded. Keep the plants free from weeds and the late planted can be hoed occasionally. The decaying leaves among Brussels Sprouts, etc., should be collected and buried in a trench.

Trenching.—Such work is often left till later on, but where the necessary labour is available the work may be taken in hand at once. It is a great help if as much as possible is completed before the New Year. The depth to which the ground is trenched depends on the district and the grower. Here we are fortunate if we can go two spits deep. A liberal quantity of manure, a sprinkling of lime, and any ash from the rubbish fire may be incorporated.

The Flower Garden.

Rose Cuttings.—Some of the stronger-growing Roses and the Rambler section will succeed on their own roots, and now is a suitable time to insert cuttings. Select well ripened wood and cut into pieces 6ins. to 8ins. in length, use a sharp knife, and trim each cutting back to a bud. A well drained border should be chosen, and the cuttings planted in lines 15ins. apart, with 6ins. between each cutting. A little sharp sand will be helpful, and the soil should be made firm by treading along the row when it is completed.

Anchusa.—The Opal and Dropmore varieties of Anchusa are splendid border plants, and the stock can be increased by root cuttings during the next month or so. Lift an old plant, select the best of the roots and cut them into 5in. or 6in. lengths. The cuttings should be inserted in boxes containing sandy soil and covered to the depth of half an inch. Place them in a cold frame or in a sheltered spot, and in due course growing points will form, which eventually will develop into fine plants. The plants should be transferred to their flowering quarters in the spring.

Anemones.—The tuberous-rooted Anemones are worthy of being grown in quantity, as they are excellent for beds and borders besides being useful for cutting. They should be planted 2ins. or 3ins. deep and from 4ins. to 6ins. apart. The planting season extends from now till March, and in heavy soils it is best to leave choice named varieties until the New Year. When making a selection, a few of the scarlet *A. fulgens* should be included, and, if planted early, flowers will appear soon after Christmas if the weather is favourable. The coronaria varieties and a good strain of the St. Brigid type are also to be recommended.

The Hardy Fruit Garden.

Autumn Fruiting Raspberries.—From various sources I learn that these are not such a success as they might be, very few canes showing signs of fruit. Now this is not entirely caused by a dry season, and the fault lies in the fact that they have been left undisturbed at the root for too long a period. With these varieties replanting annually is advised, or at least every second year, and the

work should be carried out during the autumn months. Perhaps readers will give their experience.

Raspberries.—If not already done, the old canes of the summer fruiting kinds should be removed without further delay and the weaker of the new canes cut out. These have made excellent progress this season, and care should be taken not to overcrowd them. New plantations may be made during the next few weeks, and Pyne's Royal will be found an acquisition, while the new Lloyd George is giving a good account of itself in several gardens.

Fruits Under Glass.

Peaches.—The earliest trees of both Peaches and Nectarines have ripened up their new growth and the leaves are falling, but the litter made notwithstanding, these ought not to be pulled from the trees. Syringing may cease, but the roots should not be allowed to become dry or the buds will suffer and fail to develop next year. The houses should be ventilated freely both night and day, and when an opportunity occurs any necessary pruning may be carried out.

Strawberries. Plants that were potted a few weeks ago are rooting freely, and if the weather is fine they will require water occasionally to keep the roots moist. If we get a spell of very wet weather, it will be advisable to place the plants in cold frames where they can be protected from heavy rain, otherwise they should be fully exposed.

T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.).

Castleford, Chapstow, Gloucestershire.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Celery should now be ready for the final earthing up. Draw the soil up as far as is practicable, that is, just short of smothering the tips of the central growths, and bring it up to a sharp ridge, after which beat it smooth with the back of the spade in order to throw off the winter rains. Where both red and white varieties are grown the white should be used first, as it does not keep in such good condition as the red.

Beet.—The entire crop of Beet should now be lifted and stored in ashes. Great care should be taken not to break the roots, as Beet bleeds freely when any part of the root is cut or broken. For the same reason the leaves should be wrenched off (not cut) about 2ins. above the root.

Jerusalem Artichokes.—If the stems have matured, they should be cut over a little above the ground and cleared away. It is not advisable to lift and store this crop, as the tubers are in best condition when freshly lifted.

Digging and Trenching.—As these relatively big operations have to be carried through concurrently with a number of lesser ones, the sooner a commencement is made with them the better. It is advisable either to trench or double dig (bastard trench) one-third of the whole cropping area annually, so now is the time to decide what portions are to be treated in either of the ways indicated. Ground that has been treated on the above system may be trenched or double dug at pleasure, but ground that has been somewhat neglected should be double dug for a time or two until the underspit has been improved by aeration and the introduction of organic manure.

The Hardy Fruit Garden.

Fruit Picking.—Most varieties of Apples and Pears will now be fit for picking. The work of harvesting Pears has been a light one this season, as among a general shortage of hardy fruits they have been the most disappointing. Fruit should only be picked when thoroughly dry. The fruit-room, which as a rule should not be freely ventilated, may have a little more ventilation for a week or two at present until the freshly picked fruits have "sweated out."

Strawberries.—Whatever portion of the stock is to be discarded should now be trenched down. When thus treated the decaying plants do not interfere with the succeeding crop, and they help to aerate and otherwise improve the underspit. If weeds have made their appearance among the recently planted stock, they should be removed with the aid of the Dutch hoe, selecting a dry, sunny day for the operation.

Black Currants.—The pruning of small fruits may be commenced by taking the Black Currants in hand. Young, partially developed bushes require special treatment, the aim being to build up a vigorous, well balanced bush. First cut

away all weak and badly placed shoots, and if the growth is still too thick, remove a sufficient number of even normal shoots; after which cut 6ins. or 8ins. off the tip of the leading shoots. In the case of fully developed bushes cut away a proportion of the older leading shoots and encourage vigorous young ones to take their places.

The Flower Garden.

Gladioli.—The corns should be lifted and stored. If the foliage is not quite ripened off, cut away the flower-stems and lift the corns with the foliage attached and store them in boxes among a little sand or light soil, cleaning the corns later on when the foliage has entirely died down.

Hyacinthus candicans. Lift the bulbs and store them in dry sand, and if the foliage has not quite died down, treat them on the lines recommended for Gladioli.

Annuals.—All annuals should now be cleared off, including Antirrhinums and Sweet Peas. Pentstemons, too, should be cleared away. With regard to *P. Newbury Gem*, I have proved it to be practically hardy, and when left in position a second year it makes a magnificent display. If this course is to be taken, cut over the flower-stems, and should an extra cold spell occur during the course of the winter, give the plants some protection by means of a light covering with the decayed stems of herbaceous plants.

Bedding Plants.—The whole of the bedding plants should be cleared away and the beds dug in preparation for the reception of the spring bedders. It is not advisable to apply manure at this season; this should receive attention when the ground is being dug previous to planting out the summer bedding plants.

The Pleasure Grounds.

Lawns.—If not already done, the lawns should be mown for the last time this season; this will enable the grass to make a slight growth. It is not advisable to leave lawns extremely bare during winter, as the finer grasses in that case are apt to suffer during severe wintry weather.

General Work.—Clip all grass edgings. Leaves will now be falling, so a general weekly clean-up should be given with the aid of the rake and broom. Store, when dry, tennis nets and garden furniture generally. Thoroughly clean lawn mowers and smear bearings and knives with vaseline.

CHARLES COMFORT

(Formerly Head-Gardener to Mrs. Haig, Broomfield, Davidson's Mains, Midlothian).

GREENHOUSE AND CONSERVATORY.

Gladioli of the nanus and ramosus sections are very useful for growing in pots for greenhouse decoration, also for furnishing a supply of cut flowers. As they are free-rooting plants, they require fairly large pots. Six or so of the corns should be placed in a 7in. pot. After potting, they should be stood in cold frames and kept shaded to save watering until they are well rooted and start to grow. Where they are required in quantity for cut flowers, they may be planted in boxes or even directly into cold frames.

Gladiolus Colvillei and its white variety, The Bride, are largely grown for market purposes, and they are equally useful for the private grower. There are many other fine varieties, such as Fire King, Apple Blossom, Blushing Bride, Ne Plus Ultra, Brilliant, Sappho and Fiery Knight.

Tritonia crocata has many varieties which are very beautiful plants for the cool greenhouse. They flower very freely and last for a long time. The flowers when cut are very useful for house and table decoration. *T. crocata* is a native of South Africa and requires the same cultural conditions as are accorded other South African bulbous plants, such as *Freesias* and *Lachenalias*. As the corns are very small, six or eight may be placed in a 48-sized pot. After potting, stand them in a cold frame, giving them exactly the same treatment as *Freesias*.

Ixias, of which there are so many beautiful varieties, should be potted this month, placing six or eight corns in a 48-sized pot. Afterwards stand them in cold frames, giving them exactly the same treatment as that advised for *Tritonias*. They may remain in the frames until they are coming into flower, when they should be removed to a cool, airy greenhouse. Considering how beautiful and useful they are for a supply of cut flowers, it is surprising they are not more generally grown. In the Southern Counties they can be grown outdoors in dry, warm borders, especially in front of warm walls, where during severe weather they may be given some protection. Covering them with branches answers the purpose.

Watsonia Meriana iridifolia. This beautiful white-flowered variety is very useful for the greenhouse. Four or five corms should be put in 7-in. pots, and they will grow quite well in any good potting compost. In common with most South African bulbous plants, they succeed in a cold frame until they are showing flower, when they require more head room, and at this stage should be removed to a cool greenhouse. Dry roots can generally be purchased during the winter, and should be potted up early in the New Year. There are several fine species, but they are not in cultivation at present.

Primulas of the sinensis varieties that have been growing in cold frames during the summer should now be removed to heated pits or in any greenhouse where a drier atmosphere and warmer temperature may be maintained. The most forward batches which are in their flowering pots and have filled them with roots will now benefit from weak applications of diluted liquid manure or soot water. If seed is sown at this time and the subsequent plants grown on for next year, they will make fine large specimens.

Cyclamens growing in cold frames should now be removed to a pit where they may be given a

hot heat during dull cold weather. They should be kept well up to the roof-glass and given plenty of air on all favourable occasions.

Cestrums are old favourites for greenhouse decoration, being specially useful for furnishing pillars or covering back walls. For this purpose they are best planted out in a well drained bed or border. As they are strong-growing plants, they are apt to get overrowed, and it is therefore necessary to cut out some of the older flowering wood from time to time and train in the young shoots. By this means a succession of flowers may be kept up. *C. elegans* and *Newellii* are the most common and best known species. Although not so well known, *C. aurantiacum* is equally beautiful, and probably the most useful of them all, as it succeeds better under pot cultivation than the others, and plants in 6-in. pots are now flowering for the second time this season. This species is also useful when planted out, as it makes a fine specimen, being of a more bushy and more freely branching habit than the others. These plants are easily propagated by means of cuttings of half-ripened side-shoots, which may be secured at almost any time. The plants are best stood outdoors during the summer.

Royal Botanic Gardens, Kew.

J. COULTS.

PERIODICALS

Silver-leaf Disease.—The current issue of the *Journal of Pomology** is, perhaps, exceptionally interesting. The paper on Silver-leaf Disease, in particular, will appeal to many amateurs, though to them the disease has not the life and death importance which it holds for the commercial grower. The paper is by F. T. Brooks, M.A. (University Lecturer in Botany, Cambridge), and H. H. Storey, B.A., and it represents the story of the research into peculiarities of the deadly fungus (*Stereum purpureum*) which causes so great a mortality among fruit trees. The investigators can now tell us in what lies the comparative immunity of certain varieties of Plum, for instance. The writers point out that recovery of trees infected with "Silver-leaf" is by no means uncommon and that, on several occasions it has been noticed that natural recovery from the disease has been most pronounced after a hot dry summer. They go on to say, "Pershire Plums, which readily develop silvery symptoms the first season after inoculation (with spores of *Stereum purpureum*), almost invariably recover later. Upon examination, Pershire and Victoria trees and Pear trees which have been unsuccessfully inoculated, all shew the same kind of reaction in the tissues. Where the fungus has spread appreciably in the wood there is the usual kind of discoloration, due to the type of gum which is pale in colour and takes up Delafield's hamatoxylin stain, but on the periphery is a narrow, much darker zone, containing gum of the other kind previously mentioned, which does not become stained with hamatoxylin. Sections through the invaded tissues shew hyphae, apparently dead, in the lighter discoloured zones, but not in the darker, peripheral region which has apparently formed an impenetrable barrier to the fungus. . . . It is not known how the darker gum in the outer zone is formed. . . . With the formation of a barrier of this nature, the victory of the host is complete and the diseased tissues are isolated like an island. One of the differences between the Pershire and the Victoria varieties of Plum lies in the more ready formation of this gum-barrier in the former, and with it is associated to a great extent the greater resistance of the Pershire variety to Silver-leaf disease."

They summarise treatment for this deadly malady thus: "There is no known cure for Silver-leaf disease, but every effort should be made to facilitate natural recovery of silvered trees by good cultivation and manuring. The disease can be prevented in great measure by the destruction of dead wood within and on the confines of fruit plantations on which *Stereum purpureum* might develop, by thinning and pruning fruit trees no more than is absolutely necessary and by covering exposed tissues immediately with an antiseptic such as gas tar."

Although it is disappointing to find that there is still no cure for the trouble, there are practical and helpful hints in the paper, and everyone having afflicted orchards should certainly obtain the *Journal*. Another very interesting paper is on "Red Plant" in Strawberries, by experts from the Research Station at Long Ashton. Briefly, it is shewn that "Red Plant" is caused by an eel worm, *Aphelenchus fragariae*, Ritz. Bos.

Notes on a trial of Gooseberries by the Editor, Mr. E. A. Bunyard, will also well repay study. "The Pears of New York," by U. P. Hedrick, is another paper and the book concludes with a review of a work on the Date Palm—"Dates and Date Cultivation of the Iraq," by V. H. W. Dowson. To finish as we began, it is an especially interesting number for the fruit grower.

* The *Journal of Pomology and Horticultural Science*, Vol. III, No. 3, September, 1923. Published by Hcadley Bros., 18, Devonshire Street, Bishopsgate, E.C.2, 15s. per annum, post free.

HARMONY IN THE FLOWER-BEDS

FIRST, a word as to the beds themselves. Where there is anything in the shape of a terrace harmonising with the design of the dwelling-house, some formal beds are admissible, but when we come to the sloping or undulating part of an English garden, formal beds, with the exception of circles, are not so pleasing to the eye. Indeed, to me, angular beds in such a position are an abomination. Yet we often see them. When, in the autumn, the leaves of the beautiful trees are "paling yellow or kindling into red," such beds especially mock the natural beauty.

A few flowering shrubs, Pampas Grass, Tritonias, clumps of Rambler Roses, etc., if judiciously placed, add beauty to the picture, but even this must not be overdone, for a good breadth of green-sward is a perpetual thing of beauty. Empty flower-beds in the winter are never, and full ones in the late autumn are seldom lovely. As for spring flowers, not many of them are adapted for geometrical designs. I have never yet seen spring gardening in formal beds worth looking at. I am a great lover of spring flowers, but not in regular lines or geometrical figures. Much as we deplore the forced economy in gardening matters, it is having a good effect in doing away with some of the attempts at this style of decoration.

But my principal aim in penning these notes just now is to condemn the inharmonious grouping of colours which we see in so many gardens during the summer months. Yellow *Calceolarias* and scarlet *Geraniums* seem to be an especially favourite mixture, not only in public parks and gardens of some pretensions, but also in villa gardens with only two or three beds. This is quite a savage mixture and ought not to be tolerated. Red, white and blue, although these are our national colours and are admissible at the end of a pole, have quite a harsh appearance in a flower-bed, though I do not object to these colours separately with a good breadth of green turf between them. But worse than all, which I am obliged to look on every day, is yellow and pink close together.

If people will have striking contrasts, there are several among bedding plants to choose from. I do not profess to be an artist and am open to correction, but I can tolerate purple and yellow, scarlet and purple, and even crimson and gold, though I generally prefer more moderate harmonies.

I was looking at a bed of dwarf single *Dahlias* in our beautiful Victoria Park. At first sight they appeared to be scarlet with yellow stamens,

and I wondered how it was that I enjoyed looking at them, when I came to the conclusion that the colour was too deep for scarlet and might be called crimson and the anthers were almost golden. The plants were only about a foot in height to the top of the flowers, and their name is *Coltness Gem*. There was a ring of variegated *Geraniums* round the *Dahlias* and an edging of blue *Lobelia*. Had there been an edging of the silver-leaved *Centaurea* instead of the *Geraniums* and *Lobelia*, the bed would have been perfect. Another bed which I liked from a distance, but was debarred from closely examining owing to a fence, had several plants of a large-leaved, golden-blotched *Abutilon* for a centre, single plants of *Perilla* at intervals, and was filled up with a mixture of *Begonias*, *Fuchsias* and other things. The harmony between the *Abutilon* and *Perilla* at the distance I saw it was very pleasing, but perhaps a crimson-leaved *Coleus* would have been quite as good.

Yet, not even the best of the flower-beds could approach the beauty of the trees, many of which are very large and others have striking colours. The brown, gnarled branches of an aged and large *Arbutus* is a wondrous sight, especially when the sun is shining on it. Two large trees of *Crataegus pruinifolia* are very conspicuous with their crimson leaves, especially when seen through the green leaves of the neighbouring trees. The Canadian Sugar Maple has leaves which at this time are almost the colour of old gold, and there are many other notable giants as well as dwarfs. The person who could not enjoy a ramble through this beautifully planned and well kept park is to be pitied.

The botanic garden, too, is in this park, and has a good collection of rock and other plants which are well cared for by Mr. Halliburton, and as far as I am a judge of the matter, there is not much fault to be found with the rockwork. I have never seen much of this style of gardening which satisfied me. Some years ago when visiting a well known garden, managed by one of the best men in our craft, I asked, "What are you doing with these stone heaps here?" "Stone heaps," was the reply, "this is her ladyship's special rock garden, where she spends a great deal of her time."

Stone heaps is the best name I can give to much that is called rockwork. Given a bank, the back of which is hidden so that one can imagine it is all rock behind, and it is not difficult to imitate nature to some extent, but an isolated heap of stones placed on the flat can deceive nobody.

The World is made of—

ONE big reason why Kit is indispensable to gardeners is that the world is made of dirt. Kit, the rapid action hand-soap, can dig out of the pores of the hand any dirt that can get ground into them. Ordinary dirt it laughs at; paint and tar it can shift with ease; oil and grease it can banish at the first rub.

You'll notice that Kit leaves the hands feeling clean, as well as looking clean; that's because Kit has worked deeper than ordinary soaps can.

LEVER BROTHERS LIMITED, PORT SUNLIGHT.

Genetics. The August issue of the *Journal of Genetics* (Vol. XIII, No. 2, August, 1923)* recently to hand, contains, as usual, much information of interest, alike to the student of heredity and to the amateur breeder. Perhaps it is unnecessary thus to make two classes, for the successful plant breeder must to-day be a student of heredity. The opening paper on "Inheritance of the Three Forms in Trimorphic Species," draws attention to a very interesting trait common in certain races of plants, but the conclusions on the inheritance of these diverse arrangements of the sexual organs are, so far, entirely negative. "Notes on *Fragaria*," in which the heredity of flavour in Strawberries is very fully discussed, are more practical and here certain conclusions have been reached, but the work is yet incomplete.

The most interesting paper to the plant breeder is, however, the one on the "Genetics of *Primula sinensis*," by Gregory, de Winton and Bateson. This brings information on the heredity of this plant, which has been studied so long and so usefully, quite up to date. The paper is lavishly illustrated in half-tone and colour and the very full account of the leaf variations makes exceptionally interesting reading.

TRIALS AT WISLEY

THE following awards have, we understand, been made, after trial at Wisley, by the Council of the Royal Horticultural Society.

SWEET PEAS.

Award of merit.—Elsie, sent by Messrs. Dobbie, and Anne Ireland, sent by Messrs. A. Dickson, bracketed as synonymous; Ryburgh Lemon Protee and Butterfly Spencer, both sent by Messrs. A. Stark; New Miriam Beaver, sent by Messrs. R. Veitch; Mrs. H. Richards and May Unwin, both sent by Mr. W. J. Unwin; John Ingman, sent by Messrs. Barr; Wild Rose, Charming and Liberty, all sent by Mr. J. Stevenson; George Shawyer, sent by Messrs. Dobbie; Pimpernel, sent by Messrs. E. W. King; Bunty, sent by Messrs. A. Ireland and Hitchcock; Illumination, sent by Mr. W. A. Burpee; Thos. Stevenson Improved, sent by Messrs. Morse; Gloriosa, sent by Messrs. Toogood, Messrs. R. Veitch and Messrs. Dobbie; Donald McNaughton, sent by Mr. C. Elliott; Mascott's Scarlet, sent by Messrs. R. Veitch, Messrs. Barr and Mr. Holmes; Hawlmark Scarlet, sent by Messrs. Cullen; Mrs. P. C. Tomlin, sent by Messrs. Nutting; The Cardinal, sent by Messrs. R. Veitch. (Mascott's Scarlet, Hawlmark Scarlet, Mrs. P. C. Tomlin and The Cardinal are considered synonymous.)

Highly commended.—Phyllis and John Porter, each sent by Messrs. A. Dickson and Sons and Messrs. Cullen; Mary Rose, sent by Messrs. Dobbie; Glitters, sent by Mr. W. A. Burpee; Tangerine Improved, sent by Messrs. A. Dickson, Messrs. R. Veitch, Messrs. A. Ireland and Hitchcock, and Messrs. Dobbie; Royal Salute, sent by Messrs. E. W. King and Messrs. J. K. King.

RUNNER BEANS.

Award of merit.—Bounteous, sent by Messrs. Dickson and Robinson; Prizewinner, sent by Messrs. Kelway; Colossal, sent by Messrs. Dickson and Robinson; Czar, sent by Messrs. Toogood.

Highly commended.—Scarlet Emperor, sent by Messrs. W. H. Simpson and Sons; Sir Douglas Haig, sent by Messrs. Kelway; Prizewinner, dark selection, sent by Mr. W. J. Unwin; Czar, sent by Messrs. Kelway and Messrs. W. H. Simpson and Sons; White Emperor, sent by Messrs. A. Dickson and Sons.

CLIMBERS.

Award of merit.—Blair's Prothie, Telegraph Rollison's, and Lavender, all sent by Messrs. Barr and Sons; Perfection Ridge (Ridge var.), sent by Messrs. Watkins and Simpson.

Highly commended.—Lockie's Perfection, sent by Messrs. Watkins and Simpson and Messrs. Barr; Ideal, sent by Messrs. Barr and Messrs. Dicks; Jasper Queen, sent by Messrs. G. Carpenter, Rybolt; Sensation (Ridge var.), sent by Messrs. Heinemann.

SPRING SOWN ONIONS.

Award of merit.—Silver Globe, sent by Messrs. Barr and Sons; Anglo-Spanish (sent as Giant Zittau), sent by Mr. Heinemann; Premier, sent by Messrs. Dickson and Robinson; Rousham Park Hero, sent by Messrs. Watkins and Simpson. Some eighteen varieties were highly commended or commended.

VEGETABLE MARROWS.

Highly commended.—First of All, sent by Messrs. Cooper Taber; Long Green Running, sent by Messrs. Watkins and Simpson; Green Bush (sent as Chusan Green), from Messrs. Barr and Sons; Green Bush, sent by Messrs. Nutting; Kings-Are-Cream, sent by Messrs. Barr and Sons; Moore's Cream Striped, sent by Messrs. Nutting; Rothschild Orange, sent by Messrs. W. H. Simpson and Sons.

CLIMBING FRENCH BEANS.

Award of merit.—Phenomena, sent by Messrs. Watkins and Simpson; July, sent by Messrs. Carter.

Highly commended.—Mont d'Or and Delicatessen, both sent by Messrs. Barr.

RED CURRANTS.

Award of merit.—Perfection, sent by Messrs. Laxton Bros.

Highly commended.—Comet, sent by Messrs. Laxton Bros. and Messrs. F. Harraway and Sons; Fox's New Red, sent by Messrs. Laxton Bros.

Commended.—Houghton Castle, sent by Messrs. F. Harraway; Southwell Red and Bridgetford Red, both sent by Messrs. Merryweather; Littlecroft Beauty, sent by Messrs. Whitelegg and Co. The award to Littlecroft Beauty is made for cropping qualities, but on the understanding that this variety is suited for growing only in sheltered places.

WHITE CURRANTS.

Award of merit.—White Versailles, entered by the Royal Horticultural Society.

BLACK CURRANTS.

Highly commended.—Hatton Grant, sent by Mr. H. Jones.

The Champion Potato of 1923.—Potato growers will doubtless recollect that last year Messrs. Sutton and Sons of Reading received from the Ormskirk Potato Society a certificate of merit for their early Potato Dunvegan. This was the highest award of the year, none of the varieties on trial being considered quite good enough to gain Lord Derby's gold medal offered for the finest new variety immune to the dreaded wart disease. This year, however, Messrs. Sutton have secured this supreme honour, the gold medal having been awarded to their new late Potato Ben Cinnamon (one of the Reading mm's "Ben" strain of immune varieties) in the face of keen competition from the leading Scottish and English Potato raisers. Ben Cinnamon is a very prolific white round Potato of excellent quality and is likely to be most widely grown throughout the country both for garden and field culture.

The Shortage of Roman Hyacinths.—White Roman Hyacinths, sad to relate, are extremely scarce this season. There is nothing to be done about it; the bulbs are simply non-existent. Fortunately, however, there is a good supply of the early Dutch prepared Hyacinths which make a very good substitute. They are very easily brought into bloom by January, and are much more reliable growers than the Roman Hyacinths. The best varieties of these to be had are as follows: L'Innocence (pure white), Lady Derby (rose pink), Moreno (bright pink), Gertrude (bright rose), Garibaldi (crimson), La Victoire (rosy crimson), Dr. Lieber (bright blue), Schotel (light blue), Marie (dark blue) and Yellow Hammer (yellow).

Bagatelle Rose Trials. We are informed by the Curator that a trial of new Roses will take place in the park at Bagatelle, Paris, in 1924-1925, as in previous years. New Roses should be sent to the Curator by nurserymen, together with the raiser's name, and he takes this opportunity to point out to those who think of entering that (1) The plants should, as far as possible, have been grown in pots, and several of each variety—five at least—must be sent to the Rosery at Bagatelle before April 30. A notice must be attached as to their origin and parentage, stating, if necessary, the special treatment required for the plants. (2) The plants sent will be put out in the open ground in the public Rosery immediately they reach Bagatelle. They will remain there until October of the second year so that the Jury may be able to study, through two seasons, their qualities of flower and foliage.

The Rose Trial Garden at Wisley.—The new rose trial-garden started at Wisley by the Royal Horticultural Society this year has made good progress, and plans for its further development are in hand. The director will be pleased to send entry forms for new varieties to raisers or introducers on receipt of a post-card stating the number required. The plants (six of each) should reach Wisley by November 30, and should be addressed to The Director, R.H.S. Gardens, Wisley, Ripley, Surrey (Horsley Station, Southern Railway).

FORTHCOMING EVENTS.

October 3.—United Horticultural Benefit and Provident Society's Meeting. Bath Gardeners' Society's Meeting.

October 9.—Jersey Gardeners' Society's Meeting.

October 10.—New Anglian Horticultural Society's Meeting.

October 11.—Wargrave and District Gardeners' Society's Meeting.

October 12.—Foots Cray Horticultural Society's Exhibition.

Answers to Correspondents

FLOWER GARDEN.

LILIUM CROCEUM UNSATISFACTORY (A. M. T. R.).

Some bulb mites were present and this pest may very well have caused the trouble. Subsequently, bacteria had carried on the decay. If the other bulbs are equally bad it is doubtful whether our correspondent can save them, but the mites might be killed by washing the bulbs in a solution made by dissolving 1oz. of liver of sulphur in 3 gallons of water. Our correspondent does not give details of cultural treatment. Did he have regard for the stem roots?

TREES AND SHRUBS.

SMALL-LEAVED ORNAMENTAL VINES (H. J. B.).

NEW SPRAYING MACHINES LESS THAN HALF PRICE.

An Exceptional Opportunity.

No garden, however small, is complete without a Sprayer, in fact a Sprayer is absolutely essential to obtain best results. During the War we supplied a considerable number of our well known Four Oaks Knapsack Sprayers—Rubber Diaphragm type—to the Government, and we have just re-purchased a small quantity back again, which have never been used. They are made of copper but painted Service grey colour. They have various special additions to the ordinary machines, and the price to-day would be £5 each. We guarantee them to be in perfect working order as new. We will send one machine carefully packed, carriage paid, on receipt of 50/-, but cash must accompany all orders. We would supply 2 machines for 90/-, carriage paid.

Please mention this Paper when ordering.

A BEAUTIFUL FREE BOOKLET giving full particulars and testimonials sent on receipt of postcard.

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

Cash Prices (including bags): Small (about 1 bushel), 3/-; Large (about 4 bushels), 7/-; 5 Large, 33/9; 10 Large, 65/-; 20 Large, 120/-.

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles or part beyond.

WAKELEY BROS. & CO., Ltd., 75a, Bankside, London, S.E.1

the same day as
received.

The "PERFECTOR" ARCH forms an ideal setting for the Rose Garden. The man whose pride is in his Garden will appreciate the simplicity and effectiveness of this design. The construction is light, yet strong enough for a permanency, being specially designed for the cultivation of climbing Roses, Clematis, etc. It is made entirely of OAK and treated with Solignum, size 7 ft. high above ground level, and 3 ft. 4 in. wide inside. **Price £1 each.** Orders for three or more will be sent Carriage Paid. Cash with order. These can be made wider than 3 ft. 4 in. if required, prices for which will be quoted on application, stating number required.

THE "PERFECTOR" PERGOLA.

This is constructed with the above Arches spaced any distance up to 6 ft. apart. The longitudinal and secondary cross bars to complete the Pergola are supplied in OAK, treated with Solignum, at 1/6 per foot run of Pergola; any lengths to suit your requirements. Thus the price of the Pergola illustrated, 25 ft. long, works out as follows:—

4 Arches at £1 each	£4	0	0
25 ft. run Top Bar at 1/6	£1	17	6

CARRIAGE PAID .. £5 17 6

**THE EARLY SUMMER BORDER.**

Wonderful colour harmonies can be achieved by the proper and thoughtful use of Bearded Irises and perennial Lupins in association. The distinctive characters of the two races of plants, as regards habit, foliage and flower, serve to display to best advantage the peculiar charms of both. In the picture, the Irises are comparatively dwarf varieties belonging to the variegata and squalens sections, but the stately pallida and trojana sorts are at least equally suitable for grouping with Lupins.

BARR'S Beautiful New Seedling NERINES

The most beautiful and easiest grown of Autumn-flowering Bulbs for the Greenhouse.

For autumn decoration in the greenhouse few plants can compare with Nerines for their brilliant and attractive colours. The flowers, produced in umbels of 6 to 24 blooms, are borne on stout stems from 1 to 2 feet high. The colours range from *dark red*, *vivid crimson*, *ecru* and *scarlet* to *salmon*, *coral-rose*, *pink*, *blush* and *white*, many having a glistening lustre which in sunlight gives them the appearance of being dusted with gold or silver. They remain decorative for many weeks, and their beauty may be enjoyed in a sitting-room as well as the greenhouse, if the pots are kept in a sunny window.

12 in 12 beautiful named varieties .. 42/-, 50/-, 63/- and 84/-
6 in 6 .. 18/-, 24/-, 30/- and 42/-
Mixed Hybrid Nerines (un-named) .. per doz. 25/-; each 2/6

READING

No. 2708.—VOL. LXXXVII.]

[OCTOBER 13, 1923.]

THE EARLY-FLOWERING RHODODENDRONS

The introduction of many new species, and the raising of hybrids, has made it possible to have Rhododendrons in flower most of the year.

THE normal season of flowering with several Rhododendrons is midwinter, and the number increases as the days lengthen until, during March and April, there is a wealth of blossom on many bushes. Cornish gardens in particular, and others in the South and West provided with shelter and having a mild climate, have long been famous for the culture of early-flowering Rhododendrons. It is interesting to find Rhododendron flowers being used as an advertisement to emphasise the favourable nature of the Cornish climate. The Great Western Railway displays trusses of Rhododendron flowers in early spring at its offices in London, Manchester, Liverpool, Birmingham and elsewhere to draw attention to the mild climate of the locality which they have named the Cornish Riviera.

The increasing popularity of outdoor gardening coincides with the introduction of very many new plants from China. Among these the Rhododendrons are first in point of numbers. What is far more important, however, there are a large number of really valuable additions to the most beautiful race of evergreen shrubs cultivated in our gardens. Notable additions are among the earliest and latest flowering species. Though the majority of the plants are hardy, some of the newer introductions flower early, or our changeable climate excites early growth, with disastrous results when the bushes are fully exposed to spring frosts.

While the favourable climate may be the principal reason for the successful culture of early-flowering Rhododendrons in the South and West, those who garden there are fully alive to the value of shelter and aspect. Full use is made of valleys and sloping ground, with the abundant provision of shelter belts, hedges and screens. A sprinkling of tall forest trees is generally utilised to give slight shelter to the plants in summer from the fiercest rays of the midday sun. To accommodate the thousands of new Chinese seedlings, openings or

clearances are being made in the woodland, but it is very noticeable how carefully this is done so that all the shelter and protection desirable may be preserved.

In addition to being much less expensive to maintain than greenhouses and formal bedding, owners can take a much more active interest in the trees and shrubs of the pleasure-ground beds and borders and the woodland. Next to the provision of shelter comes the question of mulching.

Rhododendrons are surface-rooting plants, so that in providing a liberal mulching of leaves, old decayed manure, bracken, etc., we are supplying the plants with food as well as material to keep the ground moist.

R. arboreum in its many seedling varieties and hybrids is the predominant plant among the Rhododendrons of the South and West during the opening months of the year. With such a vast number from which to select it is only possible

to name a very few. The first of these must be Nobleanum (arboreum caucasicum), which sometimes opens its first flowers in November, is quite good on Christmas Day, and beautiful, if the weather is mild, during January and February. R. venustum (syn. Jacksoni) is the reverse cross, a dwarf bushy plant at its best during March with beautiful rose pink flowers. The variety cinnamomeum is one of the hardiest wild forms with smaller leaves, which are cinnamon beneath, the flowers white, or pink tinted, and spotted. Cunningham's Sulphur (caucasicum \times white arboreum) is a very free-flowering dwarf bush, sometimes opening as early as the end of January and in February, while if that period is frosty the buds may open as late as April. It also has a habit of opening flowers in autumn. Harrisii (Thomsoni \times arboreum) has rosy scarlet or crimson-scarlet flowers, which often make a good show during February and March. Cornish Early Red (ponticum \times arboreum) is one of the most widely cultivated Rhododendrons in Cornwall, and there are also large specimens in Welsh, Devon and Sussex gardens. Some of the oldest are 25ft. to 30ft. in height. The flowering season varies from February to April. Russelianum, Wellsianum, altaclarensense, Bodartianum, Handsworth Early Red, Cornubia and George Cunningham are others of special value.

R. præcox (ciliatum \times dauricum) opens its bright rosy purple flowers quite early in the year. Notably free blooming and with flowers 1in. to 1½ins. across, it is a lovely plant

THE WHITE-FLOWED RHODODENDRON PRÆVERNUM.

during February and March. *R. emasculum* is somewhat mid-winter in age, but its leaves are not so deep a green in colour, and the flowers are paler and possess no stamens nor stigma. Very early propagated by cuttings, this is a really free-flowering plant which might be largely grown under glass for floral work, the flowers opening that pale creamy tint which is in such demand for wreaths and crosses.

R. damianum, more or less deciduous, and the evergreen variety *atrovirens*, frequently give a good account of themselves from January to March. In the event of possible frost the flower-buds, it shewing the rosy purple colour, open quite well when cut and placed in water. The best form of this mid-winter *Rhododendron* is var. *micronulatum*, which during mild weather in January and February is a great success in sheltered positions.

Rosa Mundi and *Christmas Cheer* are bushy evergreen *Rhododendrons* derived, presumably, in part from *R. canescens*. The bluish or pink-tinted flowers sometimes open early in the year, but more often are produced very freely in March.

R. barbatum is a Himalayan species, more hardy perhaps than *R. arboreum*, but has not been used to anything like the extent of that species as a breeder. It is rather loose-limbed in habit, but has gorgeous blood red flowers opening in March or early April. Crossed with *R. Thomsoni*, the beautiful *Shilsoni* was raised at Fremough.

R. Thomsoni is another Himalayan species with blood red flowers which requires shelter because of its early flowering. Crossed with *Fortunei* this species produced *Luscombei*, while *Ascot Brilliant* is one of the best known *Thomsoni* hybrids. Rather earlier flowering is *R. fulgens* from Nepal and Sikkim, features of which are the rich red bell-shaped flowers and the crimson bracts of the young growths.

R. lutescens when first introduced from Tibet and Western China was grown in the open. It is, however, the first of the scaly-leaved evergreen section to flower and make new growth. Suffering damage by frost for several years, the plants did very little good. Recently, spells of mild weather in February and March have allowed the pale yellow blossoms to open under favourable conditions. Several Cornish growers speak well of the plant for cutting, and in the Himalayan House at Kew several bushes grow and flower freely each year. In the hands of the hybridist *R. lutescens* offers possibilities as the parent of a useful race of early-flowering *Rhododendrons* for greenhouse culture.

Among the newer Chinese species a considerable number flower during the early months of the year. *R. sutchuenense* is one of the most distinct with large evergreen leaves and bell-shaped rosy-like flowers $\frac{1}{2}$ in. across. The typical plant is figured in the *Botanical Magazine*, Vol. 8762, which flowered at Coombe Wood in March, 1910. Since that date numerous forms have flowered varying a little in the foliage and spotting, blotching, and colour or shading of the flowers. *R. averyanum* is more compact in habit with white clothed flowers. The variety *Graddy* is another form with a distinct blotch.

R. strigillosum is notable for the bristly character of the stems, leaves, and flower stalks. The best variety has rich red flowers, but other forms have rosy, pink, and white blossoms. Not quite so conspicuous, but *R. pachytrichum* has compact trusses of pure or pale rose blossoms. There are two forms of *R. neopaniculatum*, one with rose, the other with white spotted flowers. Mr. Oulson records this species as growing in the hollow trees. It is quite hardy, but, flowering in

THE STERILE AND RATHER PALLID RHODODENDRON EMASCULUM.

THE BEAUTIFUL WHITE FORM OF RHODODENDRON MOUPINENSE.

RHODODENDRON PRECON, A LOVELY PLANT IN FEBRUARY AND MARCH.

ABOUT AUTUMN PLANTING

February and March, should be planted in sheltered positions. The plants are evergreen, of a bushy dwarf habit of growth, and the flowers open wide, suggesting a greenhouse Azalea.

I always look on RR. Fargesii, Davidii, hamatocheilum and oreodoxa as a distinct group of evergreen species with some resemblance in habit, foliage and flower. The blossoms are in each case pale rose or purplish pink. Among the scaly-leaved section R. Augustinii is one of the first to flower. The seedlings vary in colour, the most distinct and desirable being a form that has flowers of a mauve or blue shade.

The question of fuel and other expenses in connexion with the upkeep of large greenhouses and conservatories filled with exotic plants is a present-day problem in many gardens. Instead

AUTUMN planting has many advantages. It is on the whole the best season of the year to remove anything of which the transplantation presents any difficulty. However, really well transplanted and grown nursery stock will, with a few negligible exceptions, move safely even in the dead of winter. The writer well remembers planting in January several hundred Hollies, not one of which failed to grow or even "looked back." The great advantage of the next three or four weeks as a planting season lies in the possibility of starting quite an involved piece of planting and carrying it straight through to completion.

Stock will develop at its own sweet will. Such a tree can always be told by the experienced gardener from the often more poorly coloured, but thrifty, stock which bears the marks of proper nursery treatment. Those unskilled in the signs of thrifty growth should buy their stock only from a house with a reputation, and beware of plants offered at "cut" prices. In the third place, stock may often be procured at relatively low prices from bleak regions where land is of small value. Only small stock should be bought from these firms; larger plants are apt to be unshapely owing to the buffetings of the weather. A fourth method of procuring stock cheaply is to attend an auction sale where stock is being sold under the hammer to clear ground. Sometimes a real reduction may be obtained in this way, but it is well to make sure that the plants offered have been properly transplanted right up to the time of sale.

One drawback to auction sales is a weakness of human nature which we men are apt to attribute specially to the ladies, though any nursery or farm will shew the sterner sex to be equally frail in this regard. The weakness referred to is a tendency to purchase plants or, indeed, other articles of commerce, because they are cheap, not because they are the ones wanted. No garden can be properly planned in which the planting depends, not upon the kinds suitable for the work in mind, but upon those which happen to be listed in the catalogue of an auction sale. The fitness of the place for the plant and the plant for the place is the very foundation of successful planting. These notes on cheap planting have been attached to evergreens, though, as a fact, they apply with greater or less force to all classes of plants, because evergreens in general, and conifers in particular, need more attention at the hands of the nurseryman than any other classes of stock.
